

CENSUS OF INDIA 1981

OCCASIONAL PAPER
NO. 4 OF 1989

FERTILITY ESTIMATES FOR RAJASTHAN BY OWN CHILDREN METHOD

DEMOGRAPHY DIVISION
OFFICE OF THE REGISTRAR GENERAL, INDIA
MINISTRY OF HOME AFFAIRS
NEW DELHI

PREFACE

In the 1981 census three main schedules—the Houselist, the Household Schedule and the Individual Slip were canvassed. The Household Schedule consisting of two parts—Part I and Part II—was filled up in respect of every household. The first part contained information relating to the household and the second part known as the Population Record was a record of individual information on the members of the household. The household information in Part I covered household size, number of couples living in the household, housing conditions and housing amenities available to household, household ownership of house/site, land and household cultivation. Besides, it contained the religion of head of household.

The Population Record contained the list of members of the household and their social, demographic and economic characteristics as abstracted from the Individual slips. In column number three of the Population Record, provision was made to record the serial number of the mother alongwith relationship to the head in case of children upto the age ten. The present report relates to a special study to estimate fertility and its differentials by application of "own child method" undertaken in Rajasthan, on the basis of a sample of households. For this purpose children upto the age ten were tabulated according to their own age and by age of their mother. Remaining children upto the age ten whose mothers could not be identified within the household and females of the age group 15–61 were also tabulated by age. These tabulations were prepared for various characteristics such as rural/urban residence, religion and literacy etc. On the basis of these tabulations, estimates of fertility by "own children method" were prepared for different socio-economic groups.

This report has been prepared in the Demography Division by Shri K. S. Natarajan, Deputy Registrar General, India, Shri Phool Singh, Deputy Director and Dr. L. R. Yadav, Research Officer. I am thankful to the staff and officers of the Demography Division for their hard work. In particular, I am happy to place on record our appreciation of the efforts put in by Shri H. K. Kaushal, Investigator and Shri R. G. Rajan, Stenographer in bringing out this report on the Personal Computer.

A. R. NANDA
*Registrar General and
Census Commissioner, India*

*Classified by religion of the head of the household.

INTRODUCTION[†]

The decade 1970-80 witnessed an increasing awareness of the problems created by rapid population growth. With a view to stalling the rising population trend, the Government of India had during this decade introduced a number of family welfare measures. Naturally one would be interested in knowing the impact of these programmes on the fertility situation at different points of time. To measure fertility, the 1981 census had canvassed questions on children ever born to all ever married women and births during last year to all currently married women. Apart from these questions, an attempt was also made to link mothers to their children so that estimate of fertility could be worked

out by "Own child method" developed by Lee-Jay Cho and his associates of East-West Population Institute. In case of children upto age 10, provision to record the serial number of mother along-with the relationship to head in column number three of household schedule Part II was made. From this information children upto age 10 were classified by their own age and age of mother and reverse survived to estimate the number of births in previous years preceding the census. Similarly women were also classified by age and reverse survived to estimate the number of women by age for preceding years. On the basis of these two estimates, age specific fertility rates for previous years were built up.

DATA AND METHODOLOGY

The own children method of fertility estimation is based on 1% sample data of Rajasthan collected during 1981 census. The sample was selected at two stages. At the first stage 5% of the enumeration blocks were selected systematically. In the second stage 20% households were selected systematically from these blocks.

The final sample contained 82,986 women aged 15-61 and 1,03,137 children aged 0-10, on whom the own children analysis is based. As mentioned earlier, in 1981 census in column three of household schedule part-II pertaining to relationship to head of household, serial number of mother was recorded for all the children upto age 10. This schedule was the basic schedule from which data were abstracted. The children upto age 10 were classified by their own age and age of mother. Women of age 15 to 61 and children upto age 10 whose mother could not be identified in the household were also classified by age.

The own children method is an extension of reverse survival technique to estimate age specific fertility rates. In this method both women and children are reverse survived keeping in view the mortality conditions prevailing during the period for which women or children are reverse survived. Before reverse surviving some adjustments have to be made in basic data. First the tabulated number of children have to be inflated age-wise by the ratio of total number of children classified by their own age and mother's age to total children found in the sample of that particular age. This was necessary so that all children are accounted for. Implicit in this pro-rata adjustment is the assumption that children not living with their mothers in the household have same age distribution as the other children identified with their mother. Second adjustment has to be made for undercount in different ages. These adjustment-factors have been taken from post enumeration check survey for women of ages 15-61 and for children ages 5 to 10. For children of ages 0-4 under count factors were taken from census evaluation study. Table 3 shows the undercount factors for children of age 0-10 and women of age 15-61. For reverse surviving the children as well as women, life tables based on sample registration scheme for the years 1972-75 and 1976-1980 were used. The age specific fertility rates based on SRS are not available for years prior to 1972. Children as well as women can be reverse survived by assuming either constant mortality or changing mortality. With the help of these two life tables, values of nq_x , L_0 and L_{80+} were calculated by linear interpolation for 1970, 1971....1980. Life tables for 76-80 and 72-75 have been presented in table 2. Using year wise values of nq_x , L_0 and L_{80+} children were reverse survived to estimate the number of births by age of mother for different years preceding the census. Using the values of nq_x , L_0 and L_{80+} , relating to

females, women were reverse survived to estimate the number of women by age at different points of time i.e. one year prior to census or two years prior to census etc. Age specific fertility rates were worked out on the basis of these two estimates for different years prior to census.

To have accurate results from the own children method, following conditions must be fulfilled.

- (i) Proportion of those children, whose mothers could not be identified in the household should be very low.
- (ii) Moderately low and constant mortality.
- (iii) Low migration rate during the period for which estimates are prepared and
- (iv) Age reporting must be accurate.

From the tabulated data it can be observed that percentages of the children up to age 10 whose mother's could not be identified within the household were considerably low, being 2.24, 2.36 and 1.58 for total, rural and urban areas respectively. The value of expectation of life at birth was 48.4 years during 1972-75 and 51.9 years during 1976-80. From this it is clear that mortality in Rajasthan is declining very slowly over a period of time. As far as migration rates are concerned inter censal inter state migration rates (both immigration rate and outmigration rate) are lower in Rajasthan than most of the other Indian states/UTs. In this way the first three conditions are met to a large extent. As regards the accuracy of age reporting it may be pointed out that misreporting of age can be of two types.

- (i) Age misreporting in case of children of ages 0-10 and
- (ii) Age misreporting in case of women of ages 15-61.

Misreporting of age in case of children ages 0-10 is more serious than the other because misreporting of children's age affects total fertility rate directly. From figure 1 (age pyramid of Rajasthan) it can be observed that age 1, 7 & 9 are under reported with the results, estimates of total fertility rates for 1979, 1973 and 1971 may be on lower side. Number of children reported in ages 8 and 10 seems to be relatively high, making TFR estimates for 1972 and 1970 relatively high.

Misreporting of women's age have less serious effects on own children fertility estimates because of the logic of matching. If for example there is a heaping of women at age 40, there will not be only too many women ages 40 but also too many matched children of women aged 40. Therefore the child women ratio at 40 will remain unaffected. In effect, the own children method transforms this child women ratio into age specific fertility rate by means of adjustments for mortality and non-own children.

Among the methods applied to examine the quality of age data, one is Whipple's index of concentration which measures the extent of concentration at ages ending in digits 0 and 5. Another one is Myer's index of digital preference which provides information about preference for individual digits as well as an overall Index. The value of Whipple's index is around 340 both for males and females and value of Myer's index (overall index) is 75.20 and 78.88 for males and females respectively. Both the index's together show high concentration at ages ending in digits 0 and 5 and strong digital preference (liking or disliking) for remaining ages.

As stated earlier, own children method of fertility estimation is an extension of child-women ratio method. The children as well as women are reverse survived, keeping in view the mortality conditions prevailing at that time. Sex wise life tables based on Sample Registration System for the period 1972-75 and 1976-80 separately for total, rural and urban areas were used for reverse surviving. Reference dates for life tables for the period 1972-75 has been taken as 1 January 1974 and for life table for the period 1976-80, as 1st July 1978. The reference date for 1981 census was 1st March 1981. By linear interpolation and extrapolation of above, life tables with reference dates 1st September 1980, 1st

September 1979....1st September 1970 for both the sexes and separately for total, rural and urban areas were prepared. Reverse survival factors for children were derived by weighting the male and female Lx's in the ratio of 1.05 : 1.00.

Own children in each age group were updated by the ratio R_i , where

$$R_i = \frac{(Own\ children + Non-own\ children)\ of\ age\ i}{own\ children\ of\ age\ i}$$

Under enumeration factors based on CES and PEC were made use of , to adjust for under enumeration.

There are two stages of calculations involved in deriving the fertility estimates besides minor adjustments made in the tabulated data. The first stage involves tabulating women by age and children by their age and their mother's age. Second stage involves calculating age specific fertility rates and total fertility rates. In case of Rajasthan first two stages were done manually while the third by using the micro-computer software (EASWESPOP) supplied by the East West Population Institute, Honolulu, Hawaii.

TOTAL FERTILITY AND AGE SPECIFIC FERTILITY

In table 1 total fertility rates based on Own Children method (OC) for calendar years 1970 to 1980 have been presented separately for total, rural and urban areas. The table shows the rate per 1000 women instead of per woman. Corresponding estimates from the Sample Registration System (SRS) and the ratios (OC/SRS) have also been presented in that table. Figure 2 shows the total fertility rates based on OC and SRS for total, rural and urban areas. The ratios OC/SRS indicate the extent of deviation of own children estimates from the SRS estimates. Barring the three years 1971, 1979 and 1980 in all other years the TFR's estimated by own children method are higher than the SRS estimates. As a consequence in the graph, curve relating to OC lies mostly above that of SRS. The SRS shows a very slow decline in TFR from a level of 6263 in 1970 to 5546 in 1980. The TFR estimates based on OC method however fluctuate. In total, rural and urban areas the total fertility rates based on OC are approximately 25% higher than SRS rates. Probably due to age misreporting in case of children of aged 0 and 1, total fertility rates for 1980 and 1979 derived by own children method seem under estimates.

One other estimate of total fertility rate is derivable from the 1981 census data on children ever born and births during last one year by the application of P/F ratio technique developed by Brass. Adjusted rates for 1980 by Brass technique are 6.1, 6.2 and 5.1 for total, rural and urban areas respectively. On comparing the 1978 total fertility rates derived from own children method to those adjusted by Brass technique for the year 1980, the own children estimates of total fertility rate seems reasonable as the corresponding rates from OC method are 6.0, 6.4 and 4.9 for 1978.

If TFR for the years 1974 to 1978 based on OC are considered, one can say that in Rajasthan fertility is falling very slowly. For the years 1970, 1971, 1972, 1973, 1979 and 1980 rates appear to be very much out of tune with rates based on SRS. This is because of heavy misreporting of age in case of children of ages 10, 9, 8, 7, 1, 0 in census as may be verified from figure 1. showing single year age pyramid for Rajasthan.

Table 4 and figure 3 show own children estimates of total fertility rates derived alternatively with and without correction factors for under enumeration. The correction factors are shown in table 3. It is clear from the table that total fertility rates, particularly for the years 1976, 1977, 1978, 1979 and 1980 increase on applying correction factors, for under enumeration. The reason is clear if one goes through the table 3 containing under enumeration factors by age. Under enumeration factors for ages 0-4 are around 10% while those for 5-10 are

around two percent. In younger ages the under enumeration factor is comparatively higher than in adult ages. Due to this, births closer to census years are inflated comparatively more than women of age 15-61, resulting an increase in total fertility rate. For years 1970 to 1975, however the correction factors have not made much difference. If level of under count would have remained same in all the ages then on applying correction factors for under enumeration would have not result in any change in the values of total fertility rates. Previous work suggests that errors in mortality estimates do not result in too much variation in fertility estimates by OC method.

In table 5 and figure 4 own children estimates of total fertility rates derived alternatively by assuming constant and declining mortality have been presented. These estimates show a difference ranging from 0% to 4% while the difference between own children estimates of total fertility rates and that based on SRS is much higher. It is therefore clear that the differences between SRS estimates and own children estimates cannot be explained by mortality.

Mortality change, under enumeration and age misreporting do affect the fertility estimates derived from OC method. As may be seen from figure 2, age misreporting also seem to result in spuriously jagged trend. Trend based on SRS seems much more consistent. But the level of fertility based on SRS seems distinctly lower.

As mentioned earlier, the trend in total fertility rates based on own children method of estimation is zig-zag. To remove the short term fluctuations, moving average method or aggregation of rates over calendar years has been used. Aggregated values of total fertility rates, based on SRS and own children method of estimation have been presented in table 6. From the table it is clear that rates based on own children method of fertility estimation are higher than SRS rates. The minimum difference between two estimates is five percent while maximum difference is 24 percent.

Age specific fertility rates for the period 1970-80, 1971-75 and 1976-80 based on SRS and own children method of fertility estimation have been presented in table 7 and figure 5. Ratio of OC to SRS has also been worked out and presented. During 1970-80 the ASFR's based on OC are on an average 9% higher than SRS ASFR's for the age range 20-49. For the age groups 20-24, 25-29 and 45-49, the difference in ASFR's based on OC and SRS is almost of the same magnitude but in case of age group 15-19 the difference is very wide. One conclusion which can be drawn on the basis of these rates is about the higher omission rate of births in SRS compared to census enumeration. In age group 15-19, the ratio is too high being 1.48. The average

for other age groups is around 1.10. Thus out of 48% difference in this age group around 10% can be attributed to the probable under registration of births in SRS like other age groups while for remaining 38% may be attributed to the following :

- (i) Mother's of age less than 15 years were recorded as of age 15-19 in census.
- (ii) Unmarried girl's of age 15-19 misstated their age as less than 15 in the census resulting in under estimation of females in the age group and consequently increase in age specific fertility.

In Rajasthan early marriage is prevalent, so considerable number of women of age less than 15 might have given births to children and reported their age as between 15-19 years in census. Since early marriage is very common, some of the unmarried females more than age fifteen, may due to sociological reasons have under reported their age in census.

In age group 25-29 the difference is 12% while in age group 30-34 the difference is 6% only. In the age groups 30-34, 35-39 the differences are 6% and 9% respectively. This fluctuation may be attributed to age misreporting, which affects census much more than SRS. In the period 1971-75, the pattern of distortion remains same as for 1970-80. It is seen that the ratios of OC/SRS are less for 76-80 in comparison to that for period 71-75 in all the age groups indicating improvement in the efficiency of SRS during later half of the decade.

Further comparisons of age specific rates based on own children method of estimation have been made with rates based on SRS fertility survey, FS (1972) and infant and child mortality survey, ICM (1978) for rural and urban areas (table 8). Fertility estimates derived from the Fertility Survey of 1972 and Infant and Child Mortality Survey 1978 are based on a question on births during the year before the survey. The 1972 Fertility Survey (FS) estimates TFR as 6.98 and 5.22 births per women for 1972 in rural and urban areas respectively. These estimates are higher than SRS but are very close to that estimates for 1971-75 by own children method (table 8). The 1978 Infant and Child Mortality (ICM) survey had estimated TFR, as 5.48 for rural and 3.86 for urban areas. For rural areas the TFR based on ICM lies between those based on OC and SRS while for urban areas the TFR based on ICM is lowest among the three.

In rural areas, for the period 1971-75, age specific fertility rates based on OC are very near to the rates based on FS-1972 except in the age groups 15-19 and 25-29 which are more prone to age misstatements. In urban areas AFSR's based on OC method are nearer to SRS rates.

For the period 1976-80 age specific fertility rates based on SRS and OC method are very close to the ASFR based on ICM-1978 survey. Surprisingly if total fertility rates for age group 20-49 are worked out on the basis of OC, SRS and ICM-1978, all

the three are in close agreement both in rural and urban areas. From the above analysis it may be concluded that age specific fertility rates derived from own children method are reliable for the period 1976-80 both in rural and urban areas while the same are usable for urban areas for the period 1971-75. Only for rural areas age specific fertility rates based on own children method are not in close agreement with SRS rates for the period 1971-75.

One of the strengths of data collected in census or retrospective surveys is that data can be tabulated by different socio-economic characteristics. This is not generally possible in registration based data. In producing such tabulations from census or surveys however, some caution is necessary regarding the time reference of the characteristics under consideration. In tabulation of age specific fertility rates derived by the own children method, the logic of matching is such that age pertains to the woman's age at the time of delivery and not at the time of census. For example, in the case of fertility rate for women aged 20-24 in 1975, 20-24 refers to age in 1975 and not in 1981 at the time of census. The situation is quite different when a characteristic such as rural urban residence is considered. Thus, in case of a fertility rate for 1975 for urban women aged 20-24, urban characteristics refers to residence in 1981, not 1975. If residence is approximately stable over time, that is residence in 1975 is in most cases the same as residence in 1981, the tabulation of fertility for urban women in 1975 has a reasonably clear meaning. This is not true for certain other characteristics, such as women's employment status (working or non-working) which changes over time and is negatively correlated with the fertility. To avoid this ambiguity and bias fertility rates by own children method have been estimated by those characteristics which are reasonably stable over time.

In table 9, age specific fertility rates and total fertility rates for various categories of women have been presented. The characteristics considered are residence (rural and urban with urban further subdivided into city and non-city urban), cultivation of land (yes or no), home ownership (yes, no), availability/non-availability of electricity to the household and religion (Hindu, Muslim, Sikh and Jain).

In Rajasthan total fertility rates in rural and urban areas are 6581 and 4962 per thousand women. Total fertility rates for city and non-city urban areas are 5047 and 4903. Generally it is expected that TFR in city areas may be less than that for non-city urban areas. In this case the trend is reverse, though the difference is only marginal.

The second point in table 9, indicates that cultivators have higher fertility than non-cultivators. Fertility among the women belonging to households having their own houses is higher in comparison to those women in households which do not have their own houses. Since households having own houses may be economically better off than those not having their own houses, one would expect that fertility should be low among the women living in their own

houses in comparison to other. One probable reason for this may be greater non-response among poorer households. Availability of electricity to household have positive impact in reducing the fertility irrespective of rural urban residence. Muslims have the highest fertility rate in Rajasthan followed by Hindus, Sikhs and Jains. In rural areas of Rajasthan the same pattern is noticed. In urban areas, Sikhs have the lowest fertility rate.

Table 10 presents the percentage distribution of tabulated women found in sample according to various characteristics. In Rajasthan about 22% households are having electricity while 78% households do not have access to availability of electricity. As mentioned earlier the availability have positive impact on reduction of fertility. In rural areas the impact is not very significant. But in urban areas where electricity is not available to only 35% households, availability of

electricity has significant role in reducing the fertility. This reduction in fertility may be due to higher economic status of households having electricity.

Age specific fertility rates as well as total fertility rates for each district of Rajasthan by own children method for 1970-80 have been presented in table 11. Total fertility rate per thousand women varies from 5092 in Bhilwara to 7329 in Jalore. In two districts i.e., Jalore and Sawai Madhopur the average total fertility rate during 1970-80 was more than 7000 i.e., 7 children per woman. Fertility rate per thousand women among the women of age group 15-19 during 1970-80 varies from 118 in Bhilwara to 185 in Bikaner. In 50% districts of Rajasthan, fertility rate among the women of age group 15-19 is more than 150 per thousand. This high fertility at younger ages may be attributed to early childhood marriage which is prevalent in Rajasthan.

MARITAL FERTILITY

Proportion married by age and rural-urban residence are available from 1971 and 1981 censuses. From these proportions, the age specific proportions married at the mid-point of the time periods 71-75, 76-80 and also as on 1-7-72 and 1-7-78 were calculated, by linear interpolation. By multiplying these interpolated values with age specific marital fertility rates have been worked out.

Table 12 presents the age specific proportions of currently married women from 1971 and 1981 censuses separately for rural and urban areas. Singulate mean age at marriage (SMAM) for rural and urban areas on the basis of 1971 and 1981 census has also been presented. During 1971-81 SMAM for females has increased by about two years in rural areas and about one year and two months in urban areas. In rural areas proportions married in age group 15-19 and 20-24 have declined while in remaining age groups i.e., 25-29 to 45-49 these proportions have

increased. In urban areas proportions have fallen in age groups 15-19, 20-24 and 25-29 and increased in remaining age groups. Increase in proportions married in older age groups may be due to reduction in widowhood due to increase in male life expectancy and increased widow remarriages.

Table 13 and figure 6 (a) & (b) shows estimates of total marital fertility rates (TMFR's) and age specific marital fertility rates (ASMFR's) by own children method. Estimates derived from the other sources have also been presented for comparison. It is noticed that fertility have declined in rural and urban areas of Rajasthan during the latter half of the decade 1971-81. In rural areas as well as in urban areas own children estimates show a steady fall in age specific marital fertility rate in all the age groups during 1976-80 compared to 1971-75. Such a declining trend is also noticed from SRS based rates.

SUMMARY

This report analyses the fertility estimates of Rajasthan derived by own children method. The estimates of fertility derived are higher than those based on SRS, particularly for the period 1971-75. During the period 1976-80, both the estimates

mostly agree, in the age groups 20-49. Fertility estimates based on own children method seem unreliable for the age group 15-19. All the available evidences indicate that in Rajasthan fertility declined more during latter half compared to the former.

Source : The SRS estimates are from SRS bulletins.

Notes : The own children estimates in this table assume declining mortality (changing life tables) and utilize correction factors for under enumeration from the 1981 Census Post Enumeration Check. In the case of the own-children estimates, calendar year extend from 1 March to 1 March, e.g., "1979" means 1 March 1969 to 1 March 1980. In the case of the SRS estimates, calendar years run from 1 January to 1 January. SRS estimates are not available for 1970 and 1971, so the 1972 estimates have been substituted. In this table and in all subsequent tables and figures, TFRs are expressed as births per thousand women.

NOTE : In the case of SRS estimates, age-specific fertility rates were first added to obtain estimates of TFRs for single calendar years; the estimated TFR for a given time period was then calculated as the unweighted average of the TFRs for single years within the period. In this table and in all subsequent tables and figures, the own children fertility estimates assume declining mortality and incorporate correction factors for underenumeration.

TABLE—7

Age specific fertility rates for Rajasthan ; own children estimates compared with SRS estimates

| Year and source of estimates | TFR | Age | | | | | | | | | m |
|------------------------------|------|-------|-------|-------|-------|-------|-------|-------|-------|----|---|
| | | 15—19 | 20—24 | 25—29 | 30—34 | 35—39 | 40—44 | 45—49 | 9 | 10 | |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | | |
| 1970—80 | | | | | | | | | | | |
| OC | 6240 | 154 | 297 | 294 | 233 | 157 | 80 | 32 | 28·72 | | |
| SRS | 5521 | 104 | 276 | 262 | 219 | 144 | 70 | 30 | 29·12 | | |
| OC/SRS | 1·13 | 1·48 | 1·08 | 1·12 | 1·06 | 1·09 | 1·14 | 1·07 | | | |
| 1971—75 | | | | | | | | | | | |
| OC | 6636 | 165 | 307 | 310 | 245 | 175 | 86 | 40 | 28·93 | | |
| SRS | 5770 | 109 | 280 | 268 | 232 | 155 | 75 | 34 | 29·23 | | |
| OC/SRS | 1·15 | 1·51 | 1·10 | 1·16 | 1·06 | 1·13 | 1·15 | 1·18 | | | |
| 1976—80 | | | | | | | | | | | |
| OC | 5353 | 130 | 271 | 258 | 198 | 127 | 65 | 22 | 28·46 | | |
| SRS | 5123 | 94 | 265 | 252 | 200 | 129 | 61 | 25 | 28·90 | | |
| OC/SRS | 1·04 | 1·38 | 1·02 | 1·02 | 0·99 | 0·98 | 1·07 | 0·92 | | | |

NOTE : m is the mean age at child bearing as calculated from the age specific fertility rates. The OC/SRS comparison ratios are calculated from more accurate estimates of ASFRs than are shown.
