Occasional Paper No. 2 of 1988
Fertility and Child Mortality Estimates
of Kerala

Demography Division
Office of the Registrar General, India

C O N T E N T S

	Page No.
Preface ..	vii
Chapter I Population and its characteristics ..	1 - 14
Chapter II Estimates of child mortality ..	15 - 26
Chapter III Estimates of fertility ..	27 - 44
TABLES ..	45 - 46
2.1 : Child mortality estimates by district ..	47 - 49
2.2 : Child mortality estimates by religion ..	50
2.3 : Child mortality estimates by the educational level of mother ..	51
2.4 : Child mortality estimates by occupation of main workers ..	52
3.1 : Fertility indices by residence and religion ..	53 - 54
3.2 : Fertility indices by residence and educational level ..	55 - 57
3.3 : Fertility indices by residence and economic activity ..	58 - 60
3.4 : ASFR's and ASMFR's by district ..	61 - 62
3.5 : GFR, GMFR, TFR and TMFR by district ..	63
3.6 : GMFR and TMFR by religion - 1971 & 1981 ..	64
3.7 : Average number of children ever born per woman in the age group 45-49 by different classifications of women ..	65

	<u>Page No.</u>
3.8 : Average number of children ever born per woman in the age group 45-49 by district ..	66
3.9 : Sex ratio of children ever born and children surviving by age group ..	67
3.10 : Sex ratio of children ever born and children surviving by different classifications of women ..	68
3.11 : Sex ratio of children ever born and children surviving by district ..	69
3.12 : Percentage of ever married/ currently married women with three or more children in different age groups ..	70
3.13 : Percentage of ever married/ currently married women with three or more children in selected age groups by different classifications of women ..	71 - 72
3.14 : Percentage of ever married/ currently married women with three or more children in the selected age groups by district ..	73
3.15 : Proportion of childless ever married women aged 50 and above by different classifications of women ..	74
3.16 : Proportion of childless ever married women aged 50 and above by district ..	75
3.17 : Distribution of currently married women by duration of marriage and religion ..	76

	<u>Page No.</u>
3.18 : Mean age of fertility schedule (\bar{m}) and ratio of fertility rates for age groups 15-19 and 20-24 (f_1/f_2) by different classifications of women	.. 77 - 78
3.19 : Mean age of fertility schedule (\bar{m}) and ratio of fertility rates for age groups 15-19 and 20-24 (f_1/f_2) by district	.. 79
3.20 : P/F ratio for various age groups by religion	.. 80
3.21 : P/F ratio for various age groups by educational level and economic activity	.. 81
3.22 : P/F ratio for various age groups by district	.. 82
3.23 : Fertility indices adjusted by P/F ratio technique	.. 83
3.24 : Unadjusted and adjusted fertility rates by different classification of women	.. 84
3.25 : Unadjusted and adjusted fertility rates by district	.. 85

P R E F A C E

In the 1981 census four questions relating to fertility were canvassed. These were age at marriage, number of children ever born, number of surviving children and whether any child was born during last one year. The first three were canvassed for all ever married women. For operational reasons the question on births during last one year was canvassed for currently married women only.

The questions were tabulated in a 20 per cent sample of enumeration blocks in states with a population of over 10 million in 1981. The fertility data collected in the 1981 census on the basis of the response to these questions in respect of Kerala have already been published. In the present report, an attempt has been made to analyse the fertility data presented in F series. In particular, this report presents estimates of female age at marriage, fertility and child mortality. The latter two estimates have been derived by indirect estimation techniques. These estimates have been presented at district level. Alongwith these district level estimates, the state level estimates of fertility and child mortality by religion, educational level and occupational level of main workers are also presented.

This report has been prepared by Demography Division under the direction of Shri K.S. Natarajan, Assistant Registrar General. I am thankful to the staff and officers of the Demography Division for their hard work. In particular, I am happy to place on record my appreciation of the efforts put in by Shri R.K. Puri, Shri Phool Singh, Deputy Directors, Shri K. Narayanan Unni, Senior Research Officer, Shri S.S. Bawa, Shri Subhash Garg, Assistant Directors and Dr. L.R. Yadav, Research Officer.

I am also thankful to Shri Brahm Dutt, Senior Technical Assistant (VT) and Shri Ramesh D. Ajbani, Senior Supervisor who prepared varitype plates of the entire manuscript which in itself is a major task to complete in such a short time and with accuracy, Shri P.K. Banerjee, Senior Technical Assistant (Rotaprint) and Shri Om Parkash, Rota Print Machine Operator, took pains to execute their part of the job i.e. printing with technical competence.

C H A P T E R - I

Population and its characteristics

Kerala is the most densely populated state in the country. In the 1981 census 25.5 million people were counted in the state which has an area of 38,863 square kilometers giving a population density of 655 persons per square kilometer. It is the only state in India where females outnumber males with a sex ratio of 1032 females per 1000 males. This sex ratio is highest in the country. The state has relatively less percentage of population living in urban areas. Only 18.74 per cent of its population live in urban areas as against 23.31 per cent at national level. It has high literacy levels. In the decade 1971-81 the state has grown by only 19.24 per cent which is the second lowest growth rate among all states. The state is known to have comparatively low levels of fertility and mortality.

The present report analyses the data on fertility and child mortality collected in the 1981 census. The inter district variations as well as the differentials by religion, educational level and worker category of the married women in fertility and child mortality are studied in detail. As a prelude to the study this chapter presents a brief analysis of some of the variables which have a bearing on the levels of fertility and child mortality. It is supplemented by a short analysis of the distributions of currently married women by religion, educational level and worker

category. This will enable the reader to appreciate the significance of the differentials in fertility and child mortality by these characteristics.

Statement 1.1 presents district wise data on the size of population, density, sex ratio, growth rate, literacy rates and proportion of urban population, Scheduled Castes and Scheduled Tribes. There are twelve districts in the state with population size varying from 0.55 million in Wayanad to 2.81 million in Quilon. In the districts of Alleppey (1248) Trivandrum (1184) and Ernakulam (1053) there are more than 1000 people living in a square kilometer. The districts with low population density are Idukki (192) and Wayanad (260) both lying in the hilly areas. Only in the hilly district of Idukki the population density is below the national average of 216 persons per sq.km.

The state has more females than males. This may be partly due to the out migration of males from the state. It is also due to higher life expectancy of females compared to males in the state. Only the districts of Wayanad (949), Idukki (963) and Ernakulam (998) have more males than females. The districts of Quilon (1126) and Trichur (1100) have the highest sex ratios in the state. In all districts the sex ratio is above the national average of 933 females per 1000 males.

The population growth rate during the decade 1971-81 shows wide fluctuations from district to district. The districts of Kottayam and Alleppey had the lowest growth rates of 10.29 percent and 10.56 per cent respectively. The districts of Wayanad (33.87 per cent) and Malappuram (29.43 per cent) shows high growth rates of population.

STATEMENT- 1.1

Population and selected indicators - 1981

State/District	Total population (000's)	Density (per sq. km.)	Sex Ratio (females per 1000 males)	Percentage decadal variation of population, 1971-81	Percentage of urban population	Percentage of literates		Percentage of	
						Males	Females	SC	ST

5. Trichur	2,440	805	1,100	+ 14.60	21.10	77.31	70.21	12.38	0.13
6. Ernakulam	2,535	1,053	998	+ 17.18	39.56	80.75	72.88	8.54	0.14
7. Idukki	972	192	963	+ 26.91	4.59	72.15	62.55	13.71	3.98
8. Kottayam	1,697	770	1,001	+ 10.29	9.37	83.96	79.35	7.03	0.90
9. Alleppey	2,350	1,248	1,050	+ 10.56	7.23	82.12	75.10	10.02	0.14
10. Quilon	2,814	609	1,126	+ 16.61	13.15	78.10	70.21	12.35	0.26
11. Trivandrum	2,596	1,184	1,030	+ 18.08	25.26	75.29	65.85	10.95	0.54
12. Wayanad	554	260	949	+ 33.87	-	64.81	51.51	3.81	17.25

With only 18.74 per cent of the population living in urban areas, the state is much behind the national average in level of urbanisation. The settlement pattern and a well developed system of land and river communication facilities may be the prime reasons for low level of urbanisation. This in turn would give the rural people comparatively better access to urban facilities leading to lesser rural-urban differentials in fertility and child mortality. As may be seen later the rural-urban fertility and mortality differentials are narrow in the state. Ernakulam is most urbanised district with 39.56 per cent of its population living in urban areas followed by Kozhikode (27.18 per cent) and Trivandrum (25.26 per cent). These districts include the three largest urban centres in the state, namely urban agglomerations of Cochin, Calicut and Trivandrum. Wayanad district does not have any urban area. In the districts of Idukki (4.59 per cent), Alleppey (7.23 per cent), Malappuram (7.40 per cent) and Kottayam (9.37 per cent), the proportion of urban population to total population is below ten percent.

The literacy is very high among both males and females. Among males 75.26 per cent are literate. The corresponding proportion among females is 65.73 per cent. These are significantly above the all India (excluding Assam) literacy rates of 46.89 per cent for males and 24.82 per cent for females. Palghat and Wayanad and with 64.81 per cent and Malappuram with 65.93

per cent literates, are the only districts with male literacy rates below 70 per cent. These districts also have the lowest female literacy rates. The districts of Kottayam, Alleppey and Ernakulam in the central part of the state have highest literacy levels for both males and females. The literacy rate for the persons aged 5 and above in these districts are 89.65 per cent, 86.58 per cent and 84.72 per cent respectively.

In the state as a whole 10.02 per cent of the population belong to Scheduled Castes and 1.03 per cent to Scheduled Tribes. The proportion of Scheduled Castes is lowest in Wayanad and highest in Palghat, the respective percentages being 3.81 and 18.41. The tribal population of the state is concentrated in the districts of Wayanad, Cannanore, Idukki and Palghat. Wayanad with 17.25 per cent of the population belonging to Scheduled Tribes has the highest proportion of tribal population followed by Idukki with 3.98 per cent.

Out of the 12.9 million females in the state 6.1 million are in the age group 15-44 years commonly termed as reproductive age group. Among them 3.7 million accounting for 60.73 per cent are married. This percentage of married females is lowest among all major states in the country. In the age groups 15-19 years and 20-24 years also the proportion of married females is very low in the

state. These low proportions indicate higher age at marriage of females compared to other parts of the country. The mean age at marriage of females in the state is higher than that of the national average is also indicated by an analysis of the data on age at marriage of currently married females collected in the 1981 census. It is seen from the data that the mean age at marriage of currently married females in the state is 19.1 years, which is more than two years above the national average. It may be borne in mind that the mean age at marriage does not represent the current levels of age at marriage. This is because, the question was canvassed for all currently married women irrespective of the time at which they got married. In all probability older age women got married at relatively younger ages. The higher female age at marriage has resulted in a lower proportion of couples with wife in the reproductive age group 15-44 years. The ratio of couples per 1000 population (with wife in the age group 15-44) has been estimated as 146 in the state against the national average of 168. Statement 1.2 presents these nuptiality indices at the district level.

STATEMENT - 1.2

Selected Nuptiality Indices - 1981

State/District	Number of females in the age group 15-44 (00's)		Percentage of married females to total females in the age groups				Mean age at marriage			Couples per 1000 population
	Total	Married	15-44		Total	Rural		Urban		
			3	4		7	8		9	
KERALA	6,101,6	3,705,3	60.73	14.13	57.86	19.1	19.0	19.5	146	
1. Cannanore	649,3	411,0	63.29	21.18	66.18	18.2	18.1	18.6	147	
2. Kozhikode	522,3	344,8	66.02	25.63	69.93	18.1	17.9	18.6	154	
3. Malappuram	546,1	383,2	70.18	34.91	75.71	17.8	17.8	17.8	160	
4. Palghat	479,0	310,2	64.77	21.94	67.03	18.3	18.2	18.8	152	
5. Trichur	603,5	342,0	56.68	9.15	52.05	19.8	19.8	20.0	140	
6. Ernakulam	612,7	345,3	56.36	5,50	46.93	20.0	19.9	20.2	136	
7. Idukki	234,0	145,5	62.18	9.81	60.75	19.3	19.3	19.4	150	
8. Kottayam	409,0	224,2	54.81	4.28	44.42	19.8	19.7	20.1	132	
9. Alleppey	569,4	319,3	56.07	5.17	47.75	19.9	20.0	19.9	136	
10. Quilon	686,6	403,5	58.76	7.30	54.20	19.6	19.6	19.8	143	
11. Trivandrum	664,7	391,0	58.83	9.36	53.34	19.9	19.7	20.2	151	
12. Wayanad	125,2	85,3	68.12	19.80	72.94	18.6	18.6	-	154	

Note:- In Columns (2) and (3) totals may not tally due to rounding
 2.Cols.(7), (8) & (9) refers to mean age at marriage of currently married females.

In the age group 15-44 years the proportion of married females varies from 54.81 per cent in Kottayam district to 70.13 per cent in Malappuram district. In all the districts the percentage is much below the corresponding national average of 80.48 percent. In the three central districts of Kottayam, Alleppey and Ernakulam, the proportions of married females in the age group 15-19, 20-24 and 15-44 are very low while in the northern districts of Cannanore and Kozhikode the proportions are relatively higher. In the southern districts of Quilon and Trivandrum, the proportions fall in between. It may be recalled that a similar pattern was observed in case of literacy also.

Regional variations similar to those in proportion married are noticed in female age at marriage also. The mean age at marriage is highest in Ernakulam district being 20.0 years for currently married females. It is only 17.8 years in Malappuram. The district of Malappuram and rural areas of Kozhikode are the only regions where the female mean age at marriage is below 18 years. The rural urban differentials in age at marriage are not very high in the state. The high age at marriage is reflected in the couple population ratio defined as the number of currently married females in the reproductive age group 15-44 years per 1000 population. Kottayam district has the lowest couple population ratio of 132 couples per 1000 population followed by Alleppey

and Ernakulam districts with 136 couples per 1000 population. Malappuram with 160 couples per 1000 population is at the other end. Even this ratio is significantly below the national average of 168 couples per 1000 population.

Statement 1.3 Distribution of currently married women by Religion, 1981

Religion	Rural		Urban	
	Currently married women (00's)	Percent-age	Currently married women (00's)	Percent-
All women	4,086,4	100.00	909,1	100.00
A. Religions				
Hindus	2,378,3	58.20	540,2	59.42
Muslims	868,2	21.24	197,4	21.71
Christians	838,8	20.53	170,2	18.72
Jains	3	0.01	9	0.10
Religion not stated	8	0.02	4	0.05
B. Scheduled Castes				
	44,86	10.98	58,4	6.43
C. Scheduled Tribes				
	510	1.25	1,0	0.11

Note: All women include women belonging to other religions.

Totals may not tally due to rounding.

Statement 1.3 presents the distribution of population by religion of the currently married women. Of the 5.0 million married females in the state 4.1 million are in rural areas and 0.9 million in urban areas. The distribution by religion is similar in both rural and urban areas. Hindus account for 58.20 per cent and 59.42 per cent respectively in rural and urban areas. The corresponding figures for Muslims are 21.24 per cent in rural areas and 21.71 per cent in urban areas. Christians constitute respectively 20.53 per cent and 18.72 of the married females in rural and urban areas of the state. Other religions do not account for any significant proportion. About 10.98 per cent in rural areas and 6.43 per cent in urban areas of the currently married females belong to Scheduled Castes. Those belonging to Scheduled Tribes form 1.25 per cent in rural areas and 0.11 per cent in urban areas.

Statement 1.4 Distribution of currently married women by educational level - 1981

Educational level	Rural		Urban	
	Currently married women (00's)	Percent-age	Currently married women (00's)	Percent-age
All Educational levels	4,086,4	100.00	909,1	100.00
Illiterate	1,268,4	31.04	182,0	20.02
Literate but below middle	1,806,2	44.20	371,6	40.88
Middle but below matric	649,0	15.88	181,9	20.01
Matric but below graduate	329,6	7.82	134,1	14.75
Graduate and above	43,2	1.06	39,5	4.34

Note: Totals may not tally due to rounding

The distribution of the married females by educational levels has been presented in statement 1.4. It is seen that in rural areas 1.3 million out of the 4.1 million married females forming 31.04 per cent, are illiterate. Those who are literate but educated below middle school level account for 44.20 per cent and those educated between middle school and matric forms 15.88 per cent. Only 1.06 per cent of the married females in the rural areas are graduates. In urban areas illiterates form only 20.02 per cent of the married females. Another 40.88 per cent are literates, educated below middle school level. The categories "middle but below matric" and "Matric but below graduate" respectively account for 20.01 per cent and 14.75 per cent of the married females in the urban areas. Another 4.34 per cent of the married females in urban areas are graduates.

Statement 1.5 Distribution of currently married women by worker category - 1981

Worker category	Rural		Urban	
	Currently married women (00's)	Percent-age	Currently married women (00')	Percent-age
1	2	3	4	5
All women	4,086,4	100.00	909,1	100.00
a) Main workers	845,1	20.68	127,6	14.04
Cultivators	45,7	1.12		
Agricultural labourers	429,8	10.52		
Manual-workers	257,6	6.30	65,0	7.15
Non-manual workers	112,0	2.74	52,6	6.89
b) Marginal workers	278,0	6.80	28,5	3.13
Cultivators	52,4	1.28		
Agricultural labourers	122,7	3.00		
Manual workers	97,4	2.38	26,8	2.94
Non-manual workers	5,5	0.14	1,7	1.19
c) Non-workers	2,963,3	72.52	753,0	82.83

Note: 1. Non-manual workers include those in occupational divisions 0-1,2,3,4. In rural areas cultivators and agricultural labourers are excluded from manual workers while in urban areas they are also included in manual workers.

2. Totals may not tally due to rounding.

Statement 1.5 presents the distribution of the married females by worker category. It is seen that non workers number 3.0 million in rural areas and 0.8 million in urban areas among the married females, constituting 72.52

rural areas and 82.83 per cent in urban areas. Main workers and marginal workers respectively form 20.68 per cent and 6.80 per cent in rural areas. The fertility tables of the census have attempted to provide some data separately for manual and non-manual workers. All persons working in occupational divisions 0-1,2,3 and 4 the professional technical and related workers administration, executive and managerial workers, clerical and related workers, have been classified as non-manual workers. Persons working in all other occupations have been included under manual workers. In rural areas however, in view of their importance, data for cultivators and agricultural labourers have been shown separately. It is seen that a large proportion of the main workers and marginal workers are agricultural labourers followed by other manual workers. In the rural areas non-manual main workers and marginal workers respectively form only 2.74 per cent and 0.14 per cent of the currently married females. In urban areas 14.04 per cent of the

married females are main workers and 3.13 per cent are marginal workers. Among both main workers and marginal workers majority are engaged in manual occupations. In urban areas the non-manual main workers and marginal workers form 6.89 per cent and 1.19 per cent respectively of the married females.

CHAPTER - II

Estimates of child mortality

The 1981 census collected data on children ever born and children surviving sexwise. The questions on children ever born and children surviving were canvassed for all ever married women. Number of children ever born and number of children surviving have been tabulated by age of the mother. These tables are available at district level separately for rural and urban areas. From these two sets of data child mortality for the years preceding 1981 can be estimated by using Brass technique.

The essence of the Brass child mortality procedure is that the proportions of children dead classified by the age of the mother could be converted into estimates of child mortality by selecting suitable multipliers (K_i). These multipliers will differ according to the fertility pattern. As an indicator of fertility pattern, Brass suggested the ratio P_1/P_2 or P_2/P_3 where P_1 , P_2 and P_3 are the average number of children ever born per woman in the age group 15-19, 20-24 and 25-29. The multipliers for converting the proportions dead into estimates of child mortality were derived by Brass, using Brass fertility polynomial. This fertility polynomial was a mathematical function and had some limitations. In view of this, the multipliers were later modified by Trussel who generated a different set of multipliers

using model fertility schedules developed by Coale and Trussel and the regional model life tables generated by Coale and Demeney. In estimating the child mortality we have used the Trussel question.

The Brass procedure as modified by Trussel helps us to estimate $q(1)$ i.e., the probability of a new born child dying before age 1, $q(2)$ i.e., the probability of a new born child dying before age 2, $q(3)$ and probability of a new born child dying before age 3, and $q(5)$ the probability of a new born child dying before age 5. In the original Brass estimation procedure it was assumed that the child mortality would remain constant for a period preceding the census (survey). This assumption was, however, relaxed later on. Coale and Trussel developed a procedure which is valid when mortality declined. The procedure assigned the estimated $q(x)$ to a few years prior to census. In other words, when mortality is declining these estimates would not refer to the year before the census but would refer to different points of time prior to census. These have been termed as YPC, i.e. years prior to census. The YPC corresponding to $q(1)$, $q(2)$, $q(3)$ and $q(5)$ are 0.78 years, 1.83 years, 3.5 years and 5.7 years respectively.

Table 2.1 shows the estimates of child mortality $q(1)$, $q(2)$, $q(3)$ and $q(5)$. While the trend indicated by these estimates seems generally satisfactory, it is noticed that in many cases, the progression of the estimates of $q(1)$, $q(2)$, $q(3)$

and $q(5)$ is not acceptable. This is true for both rural and urban areas. Obviously mortality from age 1 to age 5 will increase progressively. However, in our estimates, sometimes $q(1)$ is estimated to be higher than $q(2)$ which is not possible. Such estimates arise because of the inaccuracies in reporting of age, number of children born and surviving, small number of events reported and other factors. Brass, in his presentation had mentioned that the estimates of $q(1)$ could not be relied upon because of the small number of children born to women in this age-group leading to sampling errors. It is, therefore, necessary that the estimates of $q(1)$ are graduated. However, due to early marriage of females the objection of small number of births to women in the age-group 15-19 may not be valid for India.

In such cases where the progression has not been acceptable we have graduated the values to remove the irregularities. The graduation has been done by taking the average of values of life expectancy corresponding to $q(2)$, $q(3)$ and $q(5)$ if the values of $q(2)$, $q(3)$ and $q(5)$ were found to be all consistent. The expectations of life at birth corresponding to $q(2)$, $q(3)$ and $q(5)$ were worked out from the South Asian pattern of Model Life Tables and their average taken. Corresponding to this average value of e_0^o the value of $q(1)$ was interpolated. This interpolated value of $q(1)$ has been taken as the graduated value of $q(1)$.

In some cases, the estimates are so inconsistent with each other that it has not been possible to graduate them. Graduation in such cases would have been purely arbitrary and subjective. In such cases, the estimates have been presented without graduation.

The estimates presented in Table 2.1 are un-graduated estimates. The graduated figures, wherever graduation was considered necessary, are also shown in brackets. The discussions in the following paras are based on the graduated values.

Estimates of child mortality for the state as a whole

The graduated value of $q(1)$ which corresponds broadly to the infant mortality works out to be 52 for Kerala, $q(2)$ denoting the number of deaths by age 2 per 1000 live births is 55, $q(3)$ denoting the number of deaths by age 3 is 63, while $q(5)$ denoting the number of deaths by age 5 is 80 only. There is not a very large difference between the child mortality in the rural and the urban areas. For rural areas $q(1)$, $q(2)$, $q(3)$ and $q(5)$ are 53, 56, 66 and 83 while in urban areas the corresponding estimates are 46, 47, 54 and 71. Female child mortality is found to be consistently lower than the male child mortality upto age 5. This is in sharp contrast to the pattern available for most of the other states particularly in North India. The $q(1)$, $q(2)$, $q(3)$ and $q(5)$ estimates

for females are 48, 50, 59 and 76 as compared to 55, 59, 67 and 85 respectively for males.

As per Sample Registration System the infant mortality rate for the year 1980 is 40 for Kerala State, 41 in the rural areas and 34 in the urban areas. Compared to the SRS our estimates are higher.

Districtwise estimates

There is a very wide variation in the estimates of child mortality between the various districts of the state. The following statement classifies the districts by level of infant mortality $q(1)$.

Statement 2.1 : Districts classified by level of infant mortality

<u>Level of IMR</u>	<u>Districts</u>
Less than 40	Ernakulam, Kottayam, Alleppey
40-45	Trichur, Trivandrum, Cannanore, Quilon
46 to 55	Malappuram, Kozhikode
56 and above	Idukki, Palghat, Wayanad

Infant mortality is quite low in the districts of Ernakulam, Kottayam and Alleppey. As compared to these districts the infant mortality is quite high in Wayanad, Palghat and Idukki districts, though by All India standards the infant mortality rate even in these three districts is extremely low.

$q(2)$ is always considered to be better estimate for measurement of child mortality than $q(1)$, because of sampling fluctuations and age errors in data. Accordingly, a comparison of $q(2)$ estimates of various districts has also been attempted. Statement below classifies the various districts by level of $q(2)$.

Statement 2.2: Districts classified by level of $q(2)$

<u>Level of $q(2)$</u>	<u>Districts</u>
Less than 40	Kottayam,
40-45	Ernakulam, Alleppey, Trichur, Trivandrum
46-55	Quilon, Cannanore, Kozhikode
56 and above	Malappuram, Palghat, Idukki, Wayanad

The level of $q(2)$ in Kottayam, Ernakulam, Alleppey, Trichur and Trivandrum districts is half or less than half than that of Wayanad. The average level of $q(2)$ estimate for the state as a whole is 55. 8 districts are below this average, while 4 are above this average.

Rural-Urban differentials of child mortality

As already mentioned, the differentials in child mortality rates between the rural and urban areas of the state are not very high. For the state as whole $q(1)$ is 53 for rural areas and 46 for urban areas, $q(2)$ is 56 in rural areas and 47 in urban

areas, $q(3)$ is 66 in rural areas and 54 in urban areas while $q(5)$ is 83 in rural areas and 71 in the urban areas. The rural-urban differentials are wider in the districts of Cannanore, Palghat, Ernakulam, Idukki, Kottayam and Alleppey. Wayanad district which does not have any urban areas at all has the highest child mortality. Both as per $q(1)$ as well as $q(2)$ and also by other parameters, Wayanad has the highest child mortality in the state.

Male-Female differentials of child mortality

For the state as a whole the infant mortality rate is 55 for males and 48 for females. $q(2)$ for males is 59 and while for females it is 50. Excepting Alleppey district, female child mortality as given by $q(2)$ is less than the male child mortality in all other districts. In Alleppey district, the female child mortality $q(2)$ is estimated at 41 for males and 42 for females but the $q(3)$ and $q(5)$ estimates for females are less than those for males. The marginally higher estimates for females may be due to chance fluctuations. The differential between the two is wider in the districts of Cannanore, Kozhikode, Malappuram, Palghat, Ernakulam, Idukki and Wayanad. The female child mortality being less than the male child mortality is in sharp contrast to the position in other states of India particularly in the North where the female child mortality is

generally found to be higher than the male child mortality due to neglect of female children. The fact that the female child mortality in Kerala is substantially lower than the male child mortality corresponds to the biological fact and testifies that female children are not neglected in Kerala.

To sum-up, the above estimates lead to general conclusions as under:-

1. Child mortality in Kerala state is extremely low as compared to other states of India.
2. The female child mortality in all the districts is lower than the male child mortality.
3. It is observed that coastal districts particularly in the Southern Kerala such as Trivandurm, Quilon, Alleppey, Kottayam, Ernakulam & Trichur have got lesser child mortality than other districts.
4. Even though the child mortality is very low in the state, there is still very wide differential in the rural and urban child mortality; the mortality being much lower in the urban areas than in the rural areas.

Child mortality estimates by religion and educational level

Table 2.2 shows the estimated child mortality rates for major religions viz. Hindus, Muslims and Christians in the state. In view of the small numbers involved, child mortality has not been calculated for the other religions viz. Sikhs, Buddhists and Jains. The Jains, the Sikhs and the Buddhists number 3605, 1295 and 223 respectively in the state in 1981. Child mortality is observed

to be the lowest for Christians and the highest for Muslims. Among the Christians $q(2)$ is 44 while for Hindus it is 54 and for Muslims it is 58. $q(5)$ is 59 for Christians, 80 for Hindus and 95 for Muslims. In the rural areas the $q(2)$ value is 45 among Christians while it is of the order of 57 and 59 among the Hindus and the Muslims. One very striking observation is that there is hardly any difference between the rural and urban child mortality in case of both Christians and Muslims but the child mortality in the urban areas for the Hindus is significantly lower than that in the rural areas. For example, $q(2)$ is 45 in the rural areas and 42 in the urban areas for Christians, 59 and 57 respectively for Muslims, while for Hindus it is 57 in the rural areas and 40 in the urban areas. Among all the three religions, the female child mortality is observed to be lower than the male child mortality.

Table 2.3 shows the child mortality estimates by educational level of the mother. This table clearly brings out the impact of the mother's educational level on child mortality. As the educational level of the mother advances, child mortality rates decline very sharply. For example, the number of deaths per 1000 live births by age 2, $q(2)$, is 24 only to matriculate but below graduate mothers, while it is 37 for middle but below matric mothers, 55 for literate but below middle mothers and as high as 86 for the children

of illiterate mothers. Of 1000 live births to matriculate but below graduate mothers, 33 had died by age 5 as against 53 in case of middle but below matric mothers, 78 for literate but below middle mothers and 118 for illiterate mothers. These figures very vividly bring out the fact that educational level of the mother has a very strong and positive impact on the mortality of their offspring. Another interesting observation is that as the educational level of the mother advances the differential between male and female child mortality narrows down numerically. This statement holds good for rural and urban areas.

Child mortality by occupational levels of the worker

These estimates have been worked out for main workers only. In the rural areas, the workers had been classified into four categories viz., cultivators, agricultural labourers, manual workers and non-manual workers. In the urban areas the classification is only two-fold, namely, manual and non-manual. Non-manual workers cover workers engaged in professional, technical and related work (Administrative, executive and managerial work, clerical and related work and sales work i.e. occupational divisions 0,1,2,3 and 4). Service workers, farmers, cultivators and agricultural labourers, fisherman, hunters, loggers and related workers, production and related workers, transport equipment operators and labourers i.e., workers in

divisions 5,6,7,8 and 9 are classified as manual workers in urban areas. It may be worth remembering that in census, occupational classification is collected only for workers other than cultivators and agricultural labourers. Child mortality estimates for various types of workers are presented in Table 2.4

In the rural areas $q(1)$ is the highest for agricultural labourers (84) followed by manual workers (other than cultivators & agricultural labourers) (72), cultivators (64) and non-manual workers (36). This order remains the same for all the four indicators of child mortality of $q(1)$, $q(2)$, $q(3)$ and $q(5)$. Both male as well as female child mortality rates follow the same pattern. Thus, even in the rural areas the child mortality among non-manual workers is very low as compared to that prevailing among agricultural labourers and manual workers (other than cultivators & agricultural labourers). For example, while the number of deaths per 1000 live births by age 5 was 117 in case of children of agricultural labourers, it was 109 in case of manual workers, 86 in case of cultivators and 43 only in case of non-manual workers. That is, child mortality amongst children of agricultural labourers is about 2 1/2 times more than that amongst children of non-manual workers.

In the urban areas, the mortality amongst children of manual workers is much higher than that amongst children of non-manual workers. In urban areas manual workers include cultivators and agricultural labourers. $q(1)$ in the urban areas is 65 for manual workers and 27 for non-manual workers ; $q(2)$ is 78 for manual workers and 33 for non-manual workers, $q(3)$ is 80 for manual workers and 34 for non-manual workers, while $q(5)$ is 96 for manual workers and 38 for non-manual workers. Another appreciable feature is that in the urban areas child mortality between age 1 and age 5 had increased more rapidly in case of manual workers (from 65 to 96 only) than in case of non-manual workers (from 27 to 38 only). Even among manual workers and agricultural labourers, the female child mortality is lower than the male child mortality in both urban as well as rural areas.

CHAPTER - III

Estimates of fertility

In the 1981 census four questions relating to fertility were canvassed. These were age at marriage, number of children ever born, number of surviving children and whether any child was born during the last one year. The first three questions were canvassed for all ever married women, while the last one was canvassed only in case of currently married women. The data has been tabulated at state level by religion, educational level and economic activity of the female. The data has also been tabulated at district level separately for rural and urban areas by age group but without cross classification by religion and educational level.

The data presented in the census permits presentations of fertility indicators at state level by religion and educational level of the females. For the first time it has become possible to provide estimates of fertility levels at the district level from the census data. The fertility indicators presented herein and their definitions are as follows:-

- | | | |
|--|---|---|
| Age specific fertility rate
(ASFR) | : | The average number of children born alive during the last year per woman of a particular age group. |
| Age specific marital fertility rate
(ASMFR) | : | The average number of children born alive during the last year per married woman of a particular age group. |

- General fertility rate : The number of children
(GFR) born alive during the last year per 1000 women of child bearing ages. In 1981 tabulation, the age group 15-49 and in the 1971 tabulation the age group 13-47 have been considered as child bearing ages.
- General marital fertility rate : The number of children born
(GMFR) alive during the last year per 1000 married women of child bearing ages. In the 1981 tabulation the age group 15-49 and in the 1971 tabulation the age group 13-47 have been considered as child bearing ages.
- Total fertility rate : Total number of children
(TFR) that would have born alive per woman, had the current schedule of age specific fertility rates been applicable for the entire reproductive period. It is calculated as the sum of the age specific fertility rates in five year age groups multiplied by five.
- Total marital fertility: Total number of children
rate that would have born alive
(TMFR) per married woman had the current schedule of age specific marital fertility rates been applicable for the entire reproductive period. It is calculated as the sum of the age specific marital fertility rates in five year age groups multiplied by five.

A few limitations with regard to these indices must be noted. In the census, the question on birth during the last one year was canvassed only for currently married women for operational reasons. It was felt that in a massive operation like the census, sensitive questions as to whether there was any birth during the last one year could not be canvassed in the case of the single, widowed or divorced women. There may have been some births during the last one year before the day of enumeration to women who might have become widowed or might have been divorced subsequently but before or during the census enumeration period. Such births would not have been netted. Another class of births that would have been left out would relate to babies born during the last one year to mothers who may have died before the census date. Also, in calculating indices such as the ASFR, AS'MFR, G'MFR and GFR the mid-year population should usually be used as the denominator.

However, in the absence of any data on deaths during the last year of females, the number of females classified by age groups as reported in the census has been used as the denominator without any adjustment. The effect of these three limitations would be partly to under estimate the relevant fertility indicators. The limitations of an enquiry of this nature in which retrospective data is attempted to be collected must also be kept in mind, particularly the likelihood of omissions

of events, inaccuracies in dating of births and distortions in age reporting. These limitations would imply that the estimates of current fertility presented herein should be considered as indicative of broad trends rather than of actual levels. In latter portion of this chapter an attempt has been made to estimate the probable level of fertility by using P/F ratio technique. The method has been explained elsewhere. The estimation makes use of the data on children ever born and that of births during last year by age of women and works out a correction factor for the latter. The applicability of the method to the Kerala data has been examined later.

Table 3.1 presents the ASFR, ASMFR etc. as estimated from census data by religion for all areas and for rural and urban areas separately. It is noticed that in the state TFR is low being 2.4, 2.5 and 2.1 for total, rural and urban areas respectively. Similarly total marital fertility rate for state as whole and for its rural and urban areas is 4.0, 4.1 and 3.8. ASFR's as well as ASMFR's are higher in rural areas in each age group compared to urban areas. This pattern is also seen in case of major three religions i.e. Hindus, Muslims and Christians of the state. Fertility is highest among Muslims followed by Hindus and Christians. In case of marital fertility the TMFR is again maximum for Muslims followed by Christians and Hindus.

In table 3.2 same fertility indices (as in table 3.1) have been presented by educational level of mothers. Educational level appears to have direct impact on fertility reduction. Both in rural and urban areas fertility declines with the increase in woman's educational level. The women who are economically active (see table 3.3), have lower fertility compared to others. Similarly among working women, those, who perform non manual jobs have lower fertility than other working women. As far as rural-urban differentials are concerned the women residing in rural areas, irrespective of their educational level or economic activity, have higher fertility compared to their counter-parts residing in urban areas.

Age specific fertility and marital fertility rates separately for rural-urban areas have been presented district-wise in table 3.4. As stated earlier fertility is low in all the districts of the state. The age specific fertility rate in the age group 45-49 is generally less than ten per thousand except in Malappuram. In age group 15-19 also the ASFR is highest in this district. Except the districts of Cannanore, Kozhikode, Malappuram, Palghat and Wayanad where ASFR for age group 15-19 is around 40 per thousand in remaining districts the value of ASFR for age group 15-19 is generally less than 20 per thousand. From table 3.5 also, it may be noticed that total fertility rate is distinctly high in these five districts namely Cannanore, Kozhikode, Malappuram, Palghat and

Wayanad. The value of TFR is highest in Malappuram and lowest in Trivandrum both in rural and urban areas.

Table 3.6 shows the values of GMFR and TMFR based on 1971 and 1981 censuses according to religion. In 1971 census, the data on births during last one year was tabulated by age group 13-17, 18-22, 23-27.....43-47. The GMFR, TMFR in respect of 1971 census, therefore, relate to the age group 13-47 while those of 1981 relate to age group 15-49. However, these may not make much difference to the broad comparisons made. In comparison to 1971 fertility has declined in 1981 in Kerala. This decline is noticed in case of women of all the religions irrespective of their rural-urban residence.

Average number of children ever born (CEB) per woman in the age group 45-49 is 5.00, 5.07 and 4.69 in state and its rural-urban areas respectively (table 3.7). Number of CEB per woman is highest for Muslim women followed by Christians and Hindus. Similar to total fertility rate, the average number of CEB per woman also decreases with the increase in woman's educational level both in rural and urban areas. Working women have fewer children than others. Among working women, Women engaged in non-manual jobs have fewer children ever born. The average number of CEB varies from 5.97 in Wayanad district to 4.66 in Alleppey district. In rural areas it varies from 5.97 in Wayanad district to 4.67 in Alleppey district while in urban areas it ranges in from 5.24 in Malappuram to 4.30 in Trivandrum.

Sex ratios of CEB and children surviving (CS) by mother's age and residence have been presented in table 3.9. Sex ratios of CEB and CS in the state as a whole vary around 950 the usually expected level of sex ratios of CEB and CS. While the sex ratio of CEB is 945, that of CS is 957 indicating that more females children survive. This indicate that in the state the female children in general enjoy good health status. In the state as a whole and its rural and urban parts the sex ratios of CEB and CS increase with mother's age upto the age of 39 and then decline. The sex ratios in rural areas are higher than in urban areas for all the age groups except age group 40-44. In the latter age groups sex ratios are higher in urban areas compared to rural areas. Generally the sex ratio of CS is higher compared to the sex ratio of CEB, both in rural and urban areas which indicates higher male mortality in the state relative to female. Higher male mortality is the general pattern observed in most of the developed countries.

Table 3.10 presents the sex ratios of CEB and CS by various classifications of women separately in rural and urban areas. The sex ratio is lowest among Muslims and highest among Christians. The differences are not very significant. The sex ratio is above the state average for literate women while for illiterate women it is below average. Economically active women have reported higher sex ratio of CEB compared to non-working women. Surprisingly women who are engaged in non-manual

jobs have lower sex ratio in comparison to other working women. Sex ratio of CEB is high in rural areas compared to urban Sex ratio of CS also follows the same pattern. In almost of all type of classifications, sex ratio of CS is higher than the sex ratio of CEB.

On the basis of table 3.11 in which sex ratios of CEB and CS have been presented the maximum and minimum values of sex ratios are as under. The table also shows the district in which the maximum or minimum value occurs.

T/R/U	Sex ratio of			
	CEB		CS	
	Minimum	Maximum	Minimum	Maximum
Total	Malappuram (936)	Idukki (952)	Malappuram (938)	Idukki and Trivan- drum (967)
Rural	Malappuram (935)	Idukki (953)	Malappuram (936)	Idukki (968)
Urban	Palghat (927)	Malap- puram (933)	Kozhikode (938)	Trivan- drum (968)

As far as rural-urban differentials are concerned, in Malappuram, Kottayam and Trivandrum the sex ratios are higher in urban areas than in rural areas. In the remaining districts the reverse pattern is noticed. Higher sex ratio of CS compared to the sex ratio of CEB noticed in all the districts again confirms that in all the parts of the state female mortality is lower than male mortality.

The percentages of ever married women (EMW) having three or more children (Table 3.12) are 51.16, 49.72 and 57.47 respectively in total, rural and urban areas of the state. As expected the percentage increases with age. Except in the age groups 15-19 and 20-24 the percentage of EMW having three or more children is higher in rural areas compared to urban areas. Similar pattern can also be observed in case of currently married women (CMW) having three or more CEB. Same statistics for selected age groups of women according to different classifications have been presented in table 3.13. Religion wise, percentage of women in the age group 40-44, having three or more children is highest among Christians. When only currently married women are considered the percentage is highest among Muslims. Among literates women the percentage having three or more children decreases with increase in educational level both in rural and urban areas. In age groups beyond 25-29 the relevant percentages for EMW and CMW in rural and urban areas are lower for illiterate women compared to those who

are literate but below matric. The probable reason may be the comparatively higher response bias in case of illiterate women. The proportion of women with three or more children is lower among working women compared to all women. The proportion is still lower in case of non-manual workers.

Table 3.14 presents the same statistics as in table 3.13 but at district level, separately for rural and urban areas. The percentages is lower in rural areas of Alleppey and urban areas of Triyandrum compared to rural or urban areas of other districts. In Malappuram district (both in urban and rural areas) the overall percentage of CM and EM women having three or more children seems to be highest. In all the districts the percentage is higher in rural areas than in urban areas.

From the data on children ever born collected in census, the proportion of women who are childless can also be calculated. Since most of the women complete their reproduction by the age of fifty, the percentage of females over the age fifty who are childless, gives an indication of the proportion of females who are sterile.

From table 3.15 it may be noted that percentages of childless ever married women of age 50+ are 3.19, 3.00 and 4.01 in total, rural and urban areas of Kerala. The percentage is highest among Hindus in total, rural and urban areas and is lowest among

Christians in total and rural areas. With the increase in level of education of women, percentage childless also increases. The percentage of childless women of age 50+ among illiterates is however higher compared to those who are literate but below matric. One probable reason for this may be response bias. Childlessness is higher among working women. Among working women, those who are engaged in non-manual jobs have higher proportion of childless women.

The percentage of childless women of age 50+ is lowest in Idukki district. (Table 3.16). It is highest in rural areas of Kozhikode district and urban areas of Cannanore district. In all the districts the percentage is high in rural areas compared to urban areas.

Table 3.17 presents the distribution of CMW by duration of marriage and religion. The percentage of CMW of marriage duration less than 5 years, less than 10 years and less than 15 years is highest among Muslims and lowest among Christians. While among Muslims about 53.17 percent of all currently married women are of marriage duration less than 15 years, in case of Christians, the corresponding percentage is only 45.12. For Hindus the percentage is 48.38.

Estimation of fertility using P/F ratio technique

As already noted, the 1981 census collected data on children ever born and births during last one year. The question on children ever born was canvassed for all ever married women and that on birth during last one year canvassed for all currently married women. If one is to make an assumption that very few births have occurred to widowed and divorced females during the last one year, the births during last one year could be converted age specific fertility rates. From these two sets of data, fertility for the year 1980 can be estimated using P/F ratio technique suggested by William Brass, where P stands for the average parity of the women in a particular age group and F stands for the average parity equivalent obtained from period fertility rates and by cumulation and interpolation.

The essence of Brass fertility estimation procedure is the adjustment of the age pattern of fertility derived from information on births during last one year by the level of fertility implied by the average parity of women in age group 20-24 and 25-29. Since the current fertility has been obtained from the census question on births during last one year preceding the census the age of mother would be at time of census, not at the time of births. In other words, there would be half a year

displacement in age specific fertility rates. Brass had developed a set of multipliers which can be used in such situations. These multipliers are dependent on the values of (f_1/f_2) i.e. the ratio of the age specific fertility rate in the age group 15-19 to that in 20-24 and the mean age of fertility schedule (\bar{m}). Apart from their use in the Brass method, these two parameters have their own independent use as parameters describing the pattern of fertility curve.

The mean age of fertility schedule (\bar{m}), distinguishes populations that have their children relatively early in their reproductive period and those have them relatively later in life. These differences may be due to age at marriage or contraception or both. Adoption of contraception in older ages, reduces the values of (\bar{m}). The ratio (f_1/f_2) , indicates the steepness of the fertility curve at initial ages. If fertility rate is low in the age group 15-19, say due to postponement of marriage, the ratio (f_1/f_2) may be very small. Otherwise it may be higher.

The mean age of fertility schedule (\bar{m}), is 27.6 in Kerala and 27.7 and 27.0 in rural urban areas respectively (see table 3.18). The value of \bar{m} is lower for Hindus than Muslims, Christians and others. In case of literate women the value of \bar{m} increases with the educational level of women. The value of \bar{m} for illiterate women is however higher than that of women with educational level "Literate

but below middle". This is due to the fact that fertility of illiterate women is relatively higher even in older age groups like 40-44 and 45-49. Women engaged in manual jobs have high \bar{m} compared to others. The value of \bar{m} is higher in rural areas than urban areas, again due to the fact that fertility is relatively higher in older age groups in rural areas.

The value of f_1/f_2 i.e. the ratio of age specific fertility rate for the age group 15-19 to the age specific fertility rate of age group 20-24 is 0.171, 0.171, 0.173 respectively, for total, rural and urban areas of the state. The ratio is low because of very low fertility rate in the age group 15-19. The value of f_1/f_2 is highest in case of Muslims followed by Hindus and Christians. This is also true about rural and urban areas. The value of f_1/f_2 decreases with the increase in educational attainment of the women in total, rural and urban areas of the state. This also may be related to the fact that in the age group 15-19, ASFR decrease with increasing educational level. The value of f_1/f_2 for working women is higher compared to others. This is attributable to the lower fertility of working women in the age group 20-24 compared to non working women. Similarly the women engaged in non-manual jobs have higher value of f_1/f_2 compared to their other working counterparts.

P/F ratios according to age and religion of women have been presented in table 3.20 for total, rural and urban areas separately. Generally P/F ratios are more than unity. The P/F ratio for the age group 20-24 is lower than that of 15-19. In subsequent age groups, the ratio increases. This indicates definite fall in fertility particularly in older age groups. Generally P_2/F_2 or P_3/F_3 i.e. ratio for age groups 20-24 or 25-29 is taken as an adjustment factor.

In this case the ratio P_2/F_2 , which gives the minimum correction, has been used to adjust the fertility indicators. Use of such correction factor when there is evidence of fertility decline may result in over estimation of fertility rates. The use of P_2/F_2 minimises the extent of such over correction as fertility may not decline sharply in age group 20-24. For example the crude birth rate for Kerala, adjusted by using P_2/F_2 as a correction factor would be 28.64. As against this, the crude birth rate based on Sample Registration System for the year 1980 is 26.80. An intensive enquiry in a selected sub sample of SRS units indicated that during 1st July 1980 to 30th June, 1981, crude birth rate was under estimated in Kerala by about 2%. The true value based on SRS may be around 27.33. The extent of over estimation of crude birth rate due to using the P_2/F_2 rate may be approximately put at 4.8% i.e. $\left[\frac{(28.64 - 27.33)}{27.33} \right]$ However extent of over estimation may not be same for all sub groups or for all districts.

The adjustment factor P_2/F_2 , is lowest for Hindus followed by Christians and Muslims. The P/F ratios in rural areas are lower than those of urban areas. The P/F ratios for literate women and working women follow the same pattern of increased trend after the age group 20-24 (Table 3.21), as in case of religion.

In case of illiterate women the ratio is more or less the same in the age groups 15-19 and 20-24. P/F ratio in age group 20-24 for women who are at least graduate and for those working women who are doing non-manual jobs is less than unity. In the better case, the ratio is closer to unity when state as a whole is considered so that adjusted and unadjusted rates do not differ. In case of women who are graduate and above the results obtained by applying P_2/F_2 may not be reliable. Similarly the adjustment factor P_2/F_2 for women who are matric and above but not graduates, living in urban areas, also appears unreliable. As rural-urban differentials are concerned for all categories of women the adjustment factor P_2/F_2 is high in urban areas compared to rural areas.

P/F ratio for district as a whole and for its rural part behave in same fashion in almost all the districts (see Table 3.22). Except Malappuram in which P/F ratio in total and rural areas fluctuates in other districts P/F ratio increases steadily after age group 20-24. In urban areas also the ratio increases after age

group 20-24 in all districts except Malappuram. In Malappuram district the P/F ratios for the age groups 15-19 to 30-34 are almost constant. Following statement shows the maximum and minimum values of P_2/F_2 (adjustment factor) for total, rural and urban areas.

Maximum and Minimum values of P_2/F_2

T/R/U	Maximum	Minimum
T	1.4734 (Quilon)	1.2909 (Trichur)
R	1.4754 (Quilon)	1.2913 (Trichur)
U	1.7527 (Idukki)	1.2775 (Kottayam)

Values of age specific fertility and marital fertility rates along with GFR, GMFR, TFR and TMFR adjusted by P/F ratio method have been presented in table 3.23. The adjusted values of total fertility rate are 3.3, 3.4 and 2.9 respectively for total, rural and urban areas of the state. Even after adjustment the pattern remains the same as in the case of unadjusted fertility indices. From table 3.24 it may be noticed that trend of the fertility indices relating to women of different religious groups and of educational level remains unchanged after adjusting these by P/F ratio method. In case of women who are economically active, there is no change due to adjustment in case of non-manual

workers. However, when all workers are considered together adjustment leads to higher fertility rates.

Table 3.25 presents the unadjusted and adjusted fertility rates by district. Before adjustment in six districts the birth rate was lower than state birth rate. After adjustment all these six districts have lower adjusted birth rate than state adjusted birth rate. The districts having maximum and minimum birth rate prior to adjustment retain their original position even after adjustment. The adjusted TFR varies from 2.7 in the districts of Kottayam, Alleppey, Trichur and Ernakulam to 5.0 in Malappuram.
