FOREWORD

Under the agreement on Family Planning Communications and Marketing between the Government of India and the United States of America through the Agency for International Development (USAID), the Demographic Analysis component had been assigned to the Office of the Registrar General, India to execute. Activities under the component included training, workshops, conferences and research activities in collaboration with the East-West Center, Honolulu, Hawaii and the U.S. Bureau of Census, Washington, D.C.

The present study is an outcome of the collaborative research between the Program on Population, East-West Center and the Office of the Registrar General, India.

I thank the authors for the efforts put in by them and hope that this work will be of interest to the data users. I also thank the United States Agency for International Development and Program on Population, East-West Center for making the research work possible.

New Delhi,
April 19, 1994.

A.R. Nanda

Introduction

Reliable vital statistics at the district level are essential for meaningful decentralized population planning in India. Although India's civil registration system is a century old, the vital statistics generated from it are, unfortunately, unreliable and suffer from significant under-registration of both births and deaths.

Recognizing the need for accurate information on fertility and mortality, the Government of India initiated a large scale demographic sample survey on a pilot basis in 1964-1965. By 1969-1970, this survey had become a regular feature of India's statistical system. Popularly known as the Sample Registration System (SRS), this demographic sample survey is based on a dual recording system and provides reliable estimates of fertility and mortality at the national and state levels separately for rural and urban areas (see Swamy *et al.* 1992 for a description of the system and the most recent evaluation of the SRS). The sample size for the SRS, however, is too small to provide reliable estimates at the district level for even such crude fertility and mortality measures as the crude birth rate (CBR) and crude death rate (CDR).

Since many government plans are implemented at the district level, the demand for district level data is extraordinary. In particular, the demand has been high for the Office of the Registrar General (ORG) India, the agency responsible for carrying out the SRS, to provide estimates for aggregates below the state level. Increasing the sample size for the SRS is one obvious solution, but pursuing this solution would be very costly, both in funding and in

trained people. Instead, the ORG's initial solution was to enlarge the scope of the 1981 Population Census by asking additional questions on fertility and mortality.

The 1981 Census included two questions on fertility: the number of births during the last one year, asked for all currently married women; and the number of children ever born (CEB), asked for all ever-married women. All ever married women were also asked a question on the number of children surviving at the time of census. Together, responses to the questions on the number of children ever born and the number of children surviving provide mortality information. Undoubtedly these data suffer from misreporting due to recall lapses, but they nevertheless provide some basis for estimating fertility and mortality levels for the states and districts of India. By applying two indirect techniques (the Brass P/F ratio method and Brass's method for estimating infant and childhood mortality) to these data, the ORG has generated estimates of district-level fertility and child mortality, which are already available in two highly useful publications (Natarajan and Singh 1988; Natarajan and Puri 1988).

The present paper provides additional estimates of the 1981 fertility and mortality levels at the district level. Three additional estimation techniques were applied to estimate total fertility rates (TFRs) and one new method was used to provide estimates of the infant mortality rate (IMR) and life expectancy at birth (e_0). These new estimates were calculated because relying on any one set of estimation techniques is probably unwise when dealing with small administrative units. Further, the Brass P/F ratio method is known to overestimate fertility levels under certain conditions, as documented later in this report.

The total fertility rate (TFR) and the two most important mortality indicators, the infant mortality rate (IMR) and the expectation of life at birth (e_0), are estimated for each state and district in India. Three different sets of TFR estimates are provided in addition to Brass P/F ratio estimates. These are regression estimates of fertility produced by applying the Palmore, Gunasekaran-Palmore, and Rele methods. The district-level estimates of IMR and e_0 are derived from the child mortality (q_2) estimates by interpolating corresponding q_1 and e_0 values from the South Asian Model Life Tables and adjusting them for SRS levels of IMR and e_0 for 1981. This paper also attempts to assess the validity and reliability of different fertility estimation techniques. The district-level TFR estimates from the Brass, Palmore, Gunasekaran-Palmore, and Rele methods are compared for this purpose. Finally, on the basis of these estimates, regional variations in fertility are discussed. For discussing fertility differentials, an average of the three regression estimates of the TFR is used. These average TFR estimates turn out to be satisfactorily consistent with the corresponding SRS estimates for the major states of India. This gives us considerable confidence in our fertility estimates. Similarly, mortality differentials are also discussed by analyzing regional variations in the IMR and e_0 levels.

A brief description of the various estimation methods is presented in the following section and the results are discussed in subsequent sections. District-level estimated total fertility rates are given in Appendix I. Estimates of the infant mortality rate (IMR) and expectation of life at birth (e_0) are given in Appendix II. Several tables and maps were also

prepared and are presented in the text to help in comparing the various fertility estimation methods and discussing regional differentials in fertility and mortality.

Methodology

Fertility Estimates

Several methods are available for indirectly estimating fertility rates. Among the most commonly used methods are: (1) the Brass P/F Ratio technique (Brass 1975), (2) the Own-Children method (Cho, Retherford, and Choe 1986), and (3) several regression methods (*e.g.*, Bogue and Palmore 1964; Rele 1967; Palmore 1978; Gunasekaran and Palmore 1984; and Rele 1967 and 1987). In this report, the Brass (1975), Palmore (1978), Gunasekaran-Palmore (1984), and Rele (1967, 1987) methods are used to arrive at district-level fertility estimates for India. Each of these methods is carefully described in the sources cited above and all of them have been used frequently to estimate fertility for other countries (*e. g.*, Cho 1964; Pacheco and Engracia 1985; Palmore 1978; Palmore *et al.* 1993; Palmore, Mamas, and Arifiyatno 1993; Palmore, Sarmiento, and Gultiano 1991; and United Nations Economic and Social Commission for Asia and the Pacific 1988) as well as for India (*e. g.*, Gunasekaran and Palmore 1984; Rao, Rele, and Palmore 1987; and Rele 1987). Consequently, we provide only a brief review of each method in the following paragraphs. Our discussion of the Rele, Palmore, and

Gunasekaran-Palmore methods closely follows the explanation provided in Swamy *et al.* 1992 and Palmore *et al.* 1993.

Brass P/F Ratio Technique

The Brass fertility estimation technique adjusts the age pattern of fertility derived from information on births during the last one year by the average parity of women in the age groups 20-24 and 25-29. The 1981 census of India collected information on both the number of births during the last one year (asked of all currently married women) and the number of children ever born (asked of women who had ever been married by the time of the census). Births during the last one year provide the age pattern of fertility under the assumption that births to widowed and divorced women during the last one year were very few. The age pattern of fertility thus obtained is corrected for under-reporting using P/F ratios for the 20-24 and 25-29 age groups, where P stands for the average parity of women in a particular age group and F stands for the average parity equivalent determined by cumulating the period fertility rates obtained above.

Natarajan and Singh (1988) have already calculated district-level fertility estimates using the Brass P/F ratio technique. For the purposes of this report we have simply duplicated their estimates. For additional details about the methodology used to provide these estimates, please refer to Natarajan and Singh 1988.

Rele Method

Rele's method derives from stable population theory (Rele 1967). It postulates a linear relationship between child woman ratios (*e.g.*, the ratio of children ages 0-4 to women ages 15-49) and the Gross Reproduction Rate (GRR), which can easily be converted into the total fertility rate. The Rele method uses a family of equations instead of a single equation, with the equations all having the general form presented in Exhibit 1. One example is the Rele equation used when the life expectancy at birth is 60:

$$GRR = -0.0182 + 3.6628 \text{ CWR},$$

where CWR stands for the child woman ratio. The complete family of equations can be found in Rele 1967 and Hanenberg 1983. The TFR is calculated by multiplying the GRR by 2.05.

Exhibit 1. General Form for the Rele Method Equations

$$GRR = a_n + b_n \text{ CWR}$$

where GRR = the gross reproduction rate;
CWR = the child-women ratio (expressed per woman); and
n = the level of mortality, expressed in a life expectancy at birth

The major advantage of Rele's method is its simplicity: it requires only an estimate of the overall level of mortality and knowing the age and sex structure of the population. The child woman ratio is calculated from the age and sex composition. Given a rough estimate of the expectation of life at birth, this ratio can then be converted into an estimate of the TFR.

Like most reverse survival methods, the Rele technique is sensitive to differential under-enumeration of children and adult women. In particular, inaccurate counts of children ages 0-4 can cause under-estimates of fertility using this method. Rele recognized this problem himself, of course, and proposed a refinement of his method (Rele 1987). The method we used is somewhat different from his 1987 refinement but also attempts to correct for inaccurate counts of young children.

We calculated four child woman ratios from the 1981 census:

$$C_{0-4}/W_{15-44}$$

$$C_{5-9}/W_{20-49}$$

$$C_{0-4}/W_{15-49}$$

$$C_{5-9}/W_{20-54}$$

Then, using the district-level expectation of life at birth estimates estimated for this study and given in Appendix II, four GRR values were estimated for each district. Corresponding TFR estimates were then obtained by multiplying the GRR values by 2.05.

In India, the 0-4 age group is often seriously under-enumerated mainly due to the under-reporting of infants and age misreporting. The 5-9 age group, conversely, is often over-

estimated mainly due to age misreporting. The corresponding CWRs, and in turn TFR values, are under-estimated for the CWRs with the 0-4 age group in the numerator, and over-estimated for the 5-9 age group CWRs. To correct for this problem, we calculated two sets of modified TFR values as follows:

$$TFR_1 = [TFR_{CWR(0-4/15-44)} + TFR_{CWR(5-9/20-49)}]/2$$

$$TFR_2 = [TFR_{CWR(0-4/15-49)} + TFR_{CWR(5-9/20-54)}]/2$$

Since the 15-49 age group of women is the preferred denominator for estimating fertility in India, we chose TFR_2 as the modified Rele estimates. The Rele estimates based on the 0-4 age group CWRs refer to the average fertility rate for the five years prior to the census and the estimates using the 5-9 age group CWRs refer to the average fertility rate for the period 5-9 years before the census. Hence, the modified Rele estimates used in this report refer to about five years prior to 1981, an average for the ten years prior to the 1981 Census.

Palmore Method

The Palmore method is a modification of a technique first introduced by Bogue and Palmore in 1964. Like Rele's method, it also postulates a linear relationship between the child woman ratio, a mortality measurement, and the TFR. Unlike Rele's method, however, the Palmore method was derived empirically using census and vital registration data from countries where both data sources were sufficiently complete and accurate. The Palmore method also adds indicators to take into account differentials in marriage patterns. If marital

status data are available, the equation used to derive the Palmore method estimates is the one presented in Exhibit 2.

Exhibit 2. Equation Used by the Palmore Method

$$TFR = 12\ 0405 + 13\ 5277\ IMR + 11\ 1042\ CWR_0 - 176\ 4889\ CP_0 - 6\ 4698\ PEM$$

where IMR = the infant mortality rate;
CWR₀ = the ratio of children ages 0-4 to
1000 women ages 15-49 years;
CP₀ = the percentage of the total
population ages 0-4; and
PEM = the percentage of women ages 20-24
who have ever been married

This method requires more data than Rele's method, but the data required are usually available from censuses or surveys in their regular tabulation programs. Also, instead of using the expectation of life at birth like Rele's method, the Palmore method employs the infant mortality rate.

This method suffers from the same sensitivity as the Rele method to data quality, particularly counts of infants and children. Whereas the Rele method tends to underestimate fertility, the Palmore method tends to overestimate when the infant mortality rate has been declining rapidly.

Gunasekaran-Palmore Method

The Gunasekaran-Palmore method is also a regression method, but it uses moments of the entire female age distribution instead of the child woman ratio. The method assumes that the moments of an age frequency distribution serve as indicators of the nature of the relationship between fertility and the age distribution and, therefore, the level of fertility. Like the Palmore method, the equation was empirically derived. The Gunasekaran-Palmore model is summarized in Exhibit 3. To calculate the TFR, the GRR is multiplied by 2.05.

Exhibit 3. The Gunasekaran - Palmore Method Equation

$$\log GRR = 9.65566 - 0.37613045 \log e_0^f + 6.08957 CVAG \\ - 0.56680627 \log K_3 - 0.74030 \log \beta_2$$

- where GRR = the gross reproduction rate;
 e_0^f = life expectancy at birth for females;
CVAG = σ / μ_1 , where CVAG is the coefficient of variation of the female age distribution (not, as typically, expressed as a percentage), σ being the standard deviation and μ_1 the mean of the female age distribution;
 K_3 = μ_3 , the third cumulant (or moment) about the mean; and
 β_2 = $(K_4 / \sigma^4) + 3$, a measure of the peakedness of the distribution, where $K_4 = \mu_4 - 3 \sigma^4$ is the fourth cumulant.

The method is applicable despite suspected data errors in the age group 0-4 (a condition widely encountered in developing country data). There is no assumption of population stability but the method probably works better if there have not been very rapid fluctuations in fertility.

In summary, the Palmore, Rele, and Gunasekaran-Palmore methods are all regression techniques that rely on commonly available census or survey tabulations, whereas the Brass P/F ratio technique requires additional fertility questions. The Palmore and Rele equations rely on child woman ratios, with adjustments for mortality. The Palmore equation also adjusts for nuptiality patterns in the population. When the number of children ages 0-4 is severely over- or under-counted, both the Palmore and Rele estimates will reflect the inaccurate counts. The Gunasekaran-Palmore method, based on the whole age distribution of the female population, was designed in an attempt to get around this problem, but depending on the age distribution so much relies on relatively accurate age data.

The Palmore and Gunasekaran-Palmore methods yield estimates of fertility that are roughly an average for the five years prior to the date of the census, 2.5 years before the census. The Brass method provides an estimate for the year prior to the census. The modified Rele method estimates rates that are an average for the ten years prior to the census.

The fertility estimates for the states and districts of India from the Brass technique and three regression methods (Palmore, Gunasekaran-Palmore, and Rele) are presented in Appendix I. For the purposes of discussing fertility differentials in India, an average of the

three regression estimates is calculated and reported in Appendix I along with the above estimates.

Mortality Estimates

The infant mortality rate (IMR) and the expectation of life at birth (e_0) were also estimated for each district. As mentioned previously, the 1981 census collected information on the number of children ever born (CEB) and the number of children surviving (CS) from all ever married women. From these data, the ORG estimated various child mortality indicators (q_1 , q_2 , and q_5) at the district level using the Brass method (see Natarajan and Puri 1988). Since q_1 values from the Brass method are often not reliable, we used q_2 as our input variable to arrive at new estimates of the infant mortality rate and the expectation of life at birth.

Using the q_2 values derived from the 1981 census, corresponding q_1 and e_0 values at the district level were estimated by interpolation from the South Asian Model Life Tables. To assure that our district-level IMR and e_0 estimates were consistent with the SRS estimates, the estimates of q_1 and e_0 obtained from the model life tables were adjusted to SRS levels for the major states. For smaller states and union territories, we could not make this adjustment because the SRS does not provide estimates for those areas. The adjustment for the major states of India was carried out by inflating or deflating the state-level IMR and e_0 model life table estimates to the corresponding SRS estimates and changing the district level estimates

by the proportion for the state as a whole. In other words, we assumed that the level of under- or over-estimation of IMR and e_0 values with respect to SRS estimates was constant for all districts within the state. These IMR and e_0 estimates are presented in Appendix II.

Results, Fertility

Comparison of the Four Indirect Estimation Techniques

Part of our rationale for calculating new fertility estimates was based on the knowledge that the Brass P/F ratio technique tends to overestimate fertility under certain conditions. This part of our rationale seems to be born out by the empirical results. Tables 1 - 6 summarize the comparisons we made between the four indirect estimation techniques.

For every state except Bihar, the Brass TFR estimates for 1981 exceed the adjusted SRS figures (see Table 1). Further, the Brass TFR estimates exceed the Palmore and Gunasekaran-Palmore method estimates for most states. Even the Rele method estimates, which refer to an average for the past ten years while the Brass techniques estimates are for the one year before the census, are higher for only five states.

Table 2 summarizes the results of subtracting the TFR estimates using the various methods from each other. The first column (labeled B-P), for example, shows the difference when the Palmore method estimate is subtracted from the Brass method estimate. At the

method estimates. In general, the Brass method estimates are the highest, the Rele method estimates second highest, the Palmore method estimates second lowest, and the Gunasekaran-Palmore method estimates lowest. Since fertility in India is declining, the Brass method estimates should be the lowest and the Rele methods highest because the Brass method estimates are for the year just before the census whereas the Rele estimates are an average for the previous ten years. This leads to the conclusion that the Brass method estimates are probably not valid and, in fact, over-estimate the TFR for most districts.

In Table 3, this conclusion is further substantiated. The Brass method estimates are higher than the Palmore method estimates for most of the districts in every state except Madhya Pradesh and Uttar Pradesh. The reason these two states may be exceptions is because fertility may not have been declining as quickly there. When comparing the Brass method estimates with the Gunasekaran-Palmore method estimates, again we find the Brass estimates higher for most districts in all states except three: Andhra Pradesh, Bihar, and Maharashtra. Compared with the Rele method estimates, the Brass method estimates are not so consistently higher for the districts in each state. This is understandable since even if the Brass method estimates are over-estimates, the Rele method estimates refer to an earlier time period when fertility was higher.

The comparison of the Gunasekaran-Palmore method estimates and the Rele method estimates (in the last column of Table 3) gives the depiction one would expect. The Rele estimates are consistently higher for most districts in all of the major states. This is what we would expect because the Rele method is estimating for an earlier time period -- at least two and a half years before the time period for the Gunasekaran-Palmore estimates. Comparing the Palmore method estimates and the Rele method estimates gives a similar picture, with the Rele estimates being higher, again confirming the expected pattern of results. Finally, the comparison of the Palmore and Gunasekaran-Palmore estimates shows an inconclusive pattern: sometimes one method is higher and sometimes the other. This is also

to be expected, since this indicates no consistent bias one way or the other and both of these two methods are estimating for the same time period (2.5 years before the 1981 census).

Up to this point, we have shown only the direction of the differences in the estimates originating from the four indirect estimation techniques. The magnitude of the differences is also important. As can be seen in Table 4, for example, the Brass method

| Table 4. Distribution of Absolute Differences between TFR Estimates from Different Estimation Methods for all India (except Assam), 1981 | | | | | | | | | | | | |

estimates are more than 0.4 different from the other three estimates in more than a third of the districts (the first three percentage columns in Table 4). The three regression method estimates agree better. In fact, there are only six comparisons of the Rele method and the Gunasekaran-Palmore method with differences greater than 0.6 -- less than two percent!

The fit between the three regression method estimates becomes even better if we exclude smaller states and union territories (see Table 5). To cite just one example, the

Table 5. Distribution of Absolute Differences between TFR Estimates from Different Estimation Methods for all India (except Assam and Smaller States), 1981

(B: Brass, P: Palmore, G: Gunasekaran-Palmore, R: Rele)

agreement between the Gunasekaran-Palmore and Rele method estimates is outstanding: close to ninety percent of the differences are 0.4 or smaller. The Palmore and Gunasekaran-Palmore estimates also diverge relatively little, with close to eighty percent of the differences being 0.4 or smaller. The agreement among the three regression estimates for the larger states is partly due to the fact that these methods tend to work better for larger aggregates, perhaps due to the usually smaller impact of migration on the age distribution of areas with larger populations, for example. The improvement in fits noticed when relating the results presented in Table 5 as compared to those in Table 4 also partly results from the fact that we were unable to adjust the IMR and e_0 values to SRS levels for the smaller states and union territories because the SRS does not have the adjustment figures for these areas.

Even in Table 5, the likelihood that the Brass method is over-estimating the total fertility rates is substantiated. The Brass estimates agree best with the Rele estimates, with about two-thirds of the differences being 0.4 or less. But the Rele estimates are supposed to refer to a time period some four or more years before the time referent for the Brass estimates, hence this agreement indicates over-estimation by the Brass technique.

The comparisons summarized in Table 6, which presents the same comparisons as those in Tables 4 and 5 but for each state separately, confirm our previous statements. In general, the fit between the Brass estimates and the three regression method estimates is better in states where we suspect that fertility has not been declining as rapidly as in other states.

In addition, the Palmore and Gunasekaran-Palmore estimates agree better with the Rele estimates in the states with relatively little fertility decline before 1981. The Palmore and Gunasekaran-Palmore method estimates tend to agree better in states that we believe have undergone more fertility change prior to 1981. For the most part, then, what we are seeing is relatively close agreement between the methods regardless of the referent time period when fertility has not changed very much but agreement between the Palmore and Gunasekaran-Palmore methods in areas with fertility decline before 1981. Since the Palmore and Gunasekaran-Palmore methods refer to the same time period, this is what we should expect.

Regional and Intra-State Fertility Differentials

Having summarized the differences between the results of the four fertility estimation methods, we now move on to an overview of the fertility situation in India shortly before 1981. For this purpose, we use an average of the three regression method estimates of the total fertility rate. In other words, we averaged the estimates from the Rele, Palmore, and Gunasekaran-Palmore methods. We did this partially to simplify our description but also in the belief that any one method's estimate might be misleading and that "averaging out" errors might be advisable. We did not include the Brass method estimates in our averages because, as shown above, we believe the Brass method estimates are too high. Tables 7 - 9 and Map 1 present selected important results.

The first striking result in the district-level total fertility rates is the proportion of India's districts with very high fertility (see Table 7). Close to eighty-four percent of the districts had a total fertility rate of 4.0 or more. More than forty-five percent of the districts

| Table 7. Distribution of Districts by the Level of Average Total Fertility Rate, India, 1981 | | |
|---|----------------------------|-------------------|
| Total Fertility Rate (TFR) | Number of Districts | Percentage |
| 2.5 and under | 1 | 0.2 |
| 2.5 - 3.0 | 11 | 2.7 |
| 3.0 - 3.5 | 16 | 4.0 |

| 6.5 - 7.0 | 13 | 3.2 |
| 7.0 and above | 0 | 0.0 |
| Total | 402 | 100.0 |

had a total fertility rate greater than 5.0. Only one district had a total fertility rate less than 2.5 and only twelve had total fertility rates less than 3.0.

As shown in Tables 8 and 9, the second important result is the very wide variation in the

| Table 8. Distribution of Districts by Their Level of Average Total Fertility Rate for Major States of India, 1981 | | | | | |
|--|---|--------------|--------------|--------------|---------------|
| State | Number of Districts with Average TFR | | | | |
| | < = 3 | 3 - 4 | 4 - 5 | 5 - 6 | > 6 |
| Andhra Pradesh | 0 | 4 | 17 | 2 | 0 |
| Bihar | 0 | 0 | 1 | 27 | 3 |
| Gujarat | 0 | 3 | 13 | 3 | 0 |

| Kerala | 6 | 5 | 1 | 0 | 0 |
| Madhya Pradesh | 0 | 0 | 9 | 22 | 14 |
| Maharashtra | 0 | 7 | 17 | 2 | 0 |
| Orissa | 0 | 0 | 11 | 2 | 0 |
| Punjab | 0 | 3 | 9 | 0 | 0 |
| Rajasthan | 0 | 0 | 2 | 20 | 4 |
| Tamil Nadu | 3 | 10 | 3 | 0 | 0 |
| Uttar Pradesh | 0 | 0 | 8 | 29 | 19 |
| West Bengal | 1 | 2 | 9 | 4 | 0 |

total fertility rates: a range in total fertility rates of more than four children! While the variation is particularly high when considering India as a whole, it is also remarkable how much variation was evident in the districts within each state.

For Bihar, Haryana, Jammu and Kashmir, Madhya Pradesh, Rajasthan, and Uttar Pradesh, the distribution of district-level total fertility rates is clearly skewed toward higher rates. Kerala and Tamil Nadu, on the other hand, are two states with most district-level fertility estimates skewed towards lower rates. The remaining states are in between these two extremes (Table 8).

The within state variations in district-level fertility are highly divergent. The coefficients of variation are highest in Kerala and West Bengal (see Table 9), with Kerala having a district-level range in TFRs from 2.5 to 4.2 and West Bengal having a range of 2.4 to 5.5. Tamil Nadu and Maharashtra also show substantial variation. In general, the intra-state variability in TFRs seems to be higher in states that probably underwent fertility declines before 1981. The variation in district-level total fertility rates is less for states with high levels of fertility overall. Examples of this phenomenon are Bihar, with a range of TFRs from 4.4 to 6.4; Haryana with a range of TFRs from 4.4 to 5.9; Orissa with a range of TFRs from 4.1 to 5.4; and Rajasthan with a range of TFRs from 4.8 to 6.5.

For the whole country (except Assam), the range in district-level TFRs is from a low of 2.4 for Calcutta to a high of 6.8, shared by the Tikamgarh and Chhatarpur districts in Madhya Pradesh and the Bijnor, Maradabad, and Rampur districts in Uttar Pradesh. This

**Table 9. Intra-State Variability in Total Fertility Rates,
Major States of India, 1981**

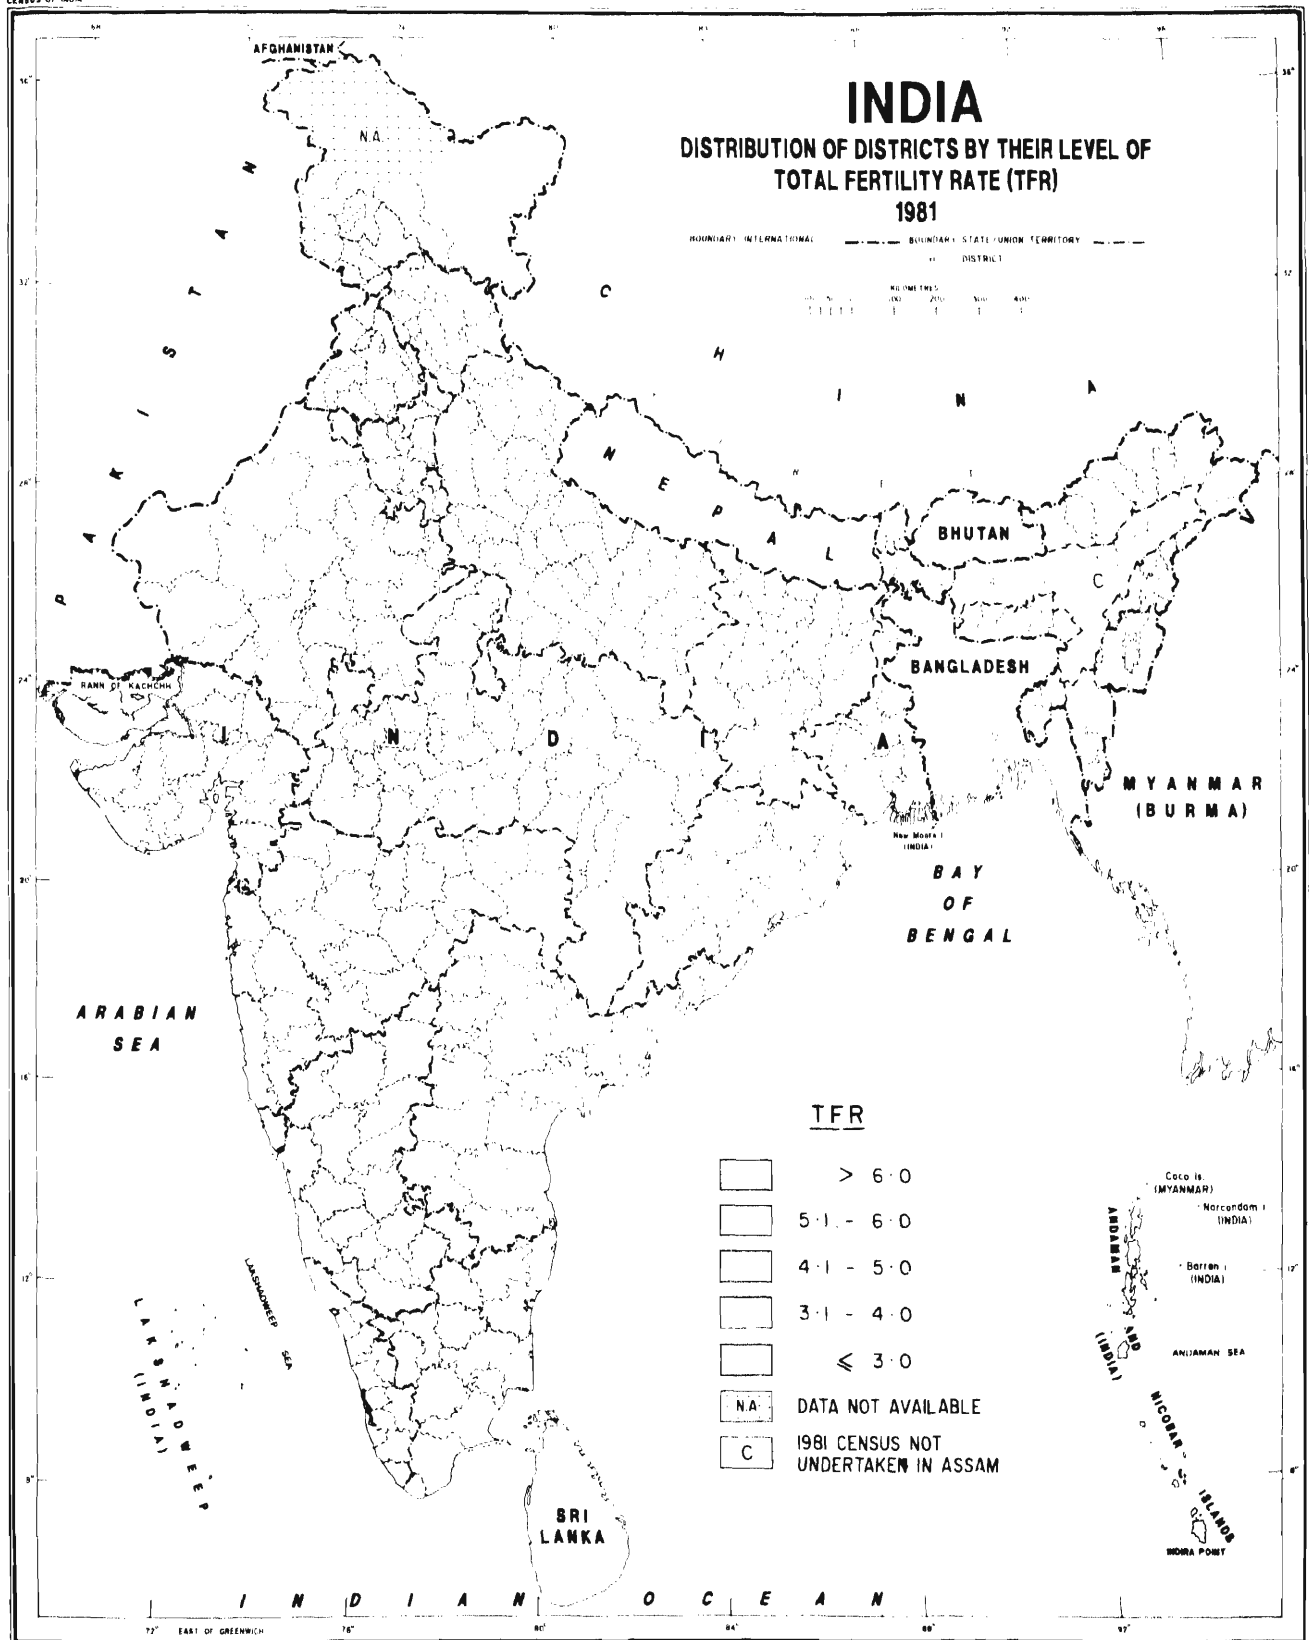

| State | Total Fertility Rate | | | | |
|------------------|----------------------|------|------|------|------|
| | TFR | Min. | Max. | S.D. | C.V. |

| Rajasthan | 5.6 | 4.8 | 6.5 | 0.4 | 7.1 |
| Tamil Nadu | 3.7 | 2.8 | 4.5 | 0.5 | 14.1 |
| Uttar Pradesh | 5.8 | 4.2 | 6.8 | 0.6 | 10.3 |
| West Bengal | 4.4 | 2.4 | 5.5 | 0.7 | 17.0 |

Note: Coefficient of Variation (C.V.) is calculated with respect to our state level TFR estimates rather than the mean of TFRs for districts in each state.

overall fertility pattern, described in the tables and paragraphs above, is perhaps best summarized in a map (Map 1).

Just before 1981, the districts with total fertility rates of 5.0 and above were clearly concentrated in Rajasthan, Haryana, Uttar Pradesh, Madhya Pradesh, and Bihar. The districts with lower fertility rates are mostly coastal areas in Maharashtra, Karnataka, Kerala, Tamil Nadu, and Andhra Pradesh. Most of the districts in the north-eastern states of Nagaland and Manipur also have relatively low TFRs. TFRs in the middle range are found in districts located in the northern states of Jammu and Kashmir, Punjab, Himachal Pradesh; the western state Gujarat; the eastern states of West Bengal and Orissa; and hinterland districts of Maharashtra, Andhra Pradesh, and Karnataka. Most of the districts of Mizoram and Tripura also fall into this middle category.

Studying the map will provide few surprises for the keen observer of Indian fertility patterns when it comes to assessing the overall pattern by state, but the variation within states and the pockets of either high or low fertility in each state stand out more when looking at the map than when looking at a rather less visually appealing table. The few districts with very high fertility in Maharashtra, Andhra Pradesh, and Orissa clearly stand out. The pockets of lower fertility in Himachal Pradesh, Jammu and Kashmir, Gujarat, and West Bengal also catch the eye. Likewise, the difference in fertility of the coastal and hinterland districts in the southern states is notable.

The territorial waters of India extend into the sea to a distance of twelve nautical miles measured from the appropriate base line.

Results, Mortality

Tables 10 - 15 summarize our new district-level mortality estimates. As one might expect, mortality conditions in India are highly variable too. The district-level infant mortality rates vary from under 30 to over 200! With an IMR of 60 as the national goal for the year 2000, it is remarkable that only 46 districts out of 402 had achieved that level by 1981 (Table 10). In

| Table 10. Distribution of Districts by the Level of the Infant Mortality Rate, India, 1981 | | |
|---|----------------------------|-------------------|
| Infant Mortality Rate (IMR) | Number of Districts | Percentage |
| 20 and under | 0 | 0.0 |
| 20 - 40 | 13 | 3.2 |
| 40 - 60 | 33 | 8.2 |
| 60 - 80 | 61 | 15.2 |
| 80 - 100 | 90 | 22.4 |
| 100 - 120 | 64 | 15.9 |
| 120 - 140 | 62 | 15.4 |
| 140 - 160 | 48 | 11.9 |
| 160 - 180 | 22 | 5.5 |
| 180 - 200 | 6 | 1.5 |
| 200 and above | 3 | 0.7 |
| Total | 402 | 100.0 |

fact, more than one third of the districts had IMRs greater than 120.

Districts in Bihar, Gujarat, Madhya Pradesh, Orissa, and Uttar Pradesh tended to have higher infant mortality rates than most states (Table 11). At the other extreme, districts in

| Table 11. Distribution of Districts by Their Level of Infant Mortality Rate for Major States of India, 1981 | | | | | |
|--|-------------------------------------|----------------|-----------------|------------------|-----------------|
| State | Number of Districts with IMR | | | | |
| | < = 40 | 40 - 80 | 80 - 120 | 120 - 160 | > 160 |
| Andhra Pradesh | 1 | 5 | 16 | 1 | 0 |
| Bihar | 0 | 1 | 16 | 14 | 0 |
| Gujarat | 0 | 0 | 8 | 11 | 0 |
| Haryana | 0 | 0 | 11 | 1 | 0 |
| Himachal Pradesh | 0 | 8 | 4 | 0 | 0 |
| Jammu & Kashmir | 0 | 9 | 4 | 1 | 0 |
| Karnataka | 0 | 18 | 1 | 0 | 0 |
| Kerala | 8 | 4 | 0 | 0 | 0 |
| Madhya Pradesh | 0 | 0 | 3 | 32 | 10 |
| Maharashtra | 0 | 9 | 17 | 0 | 0 |
| Orissa | 0 | 0 | 3 | 10 | 0 |
| Punjab | 0 | 5 | 7 | 0 | 0 |
| Rajasthan | 0 | 3 | 16 | 7 | 0 |
| Tamil Nadu | 0 | 4 | 12 | 0 | 0 |
| Uttar Pradesh | 0 | 0 | 8 | 29 | 19 |
| West Bengal | 0 | 7 | 7 | 2 | 0 |

Himachal Pradesh, Jammu and Kashmir, Karnataka, Kerala, Maharashtra, Punjab, and West Bengal had lower infant mortality rates. Among these states, Kerala clearly stands out as having the lowest IMRs.

As was true for fertility rates, there is substantial intra-state variation in infant mortality rates (Table 12). Within state variability in IMR levels is highest in Jammu and Kashmir, with a coefficient of variation of 30.5. In that state, the district-level IMRs range from a low of 44 in Srinagar district to a high of 142 in Kargil district. Kerala, West Bengal, Maharashtra, and Himachal Pradesh also have relatively high levels of variability. Again as was true for fertility rates, it appears that within state variability in IMRs is usually greater in states where the IMR appears to have been declining more rapidly prior to 1981.

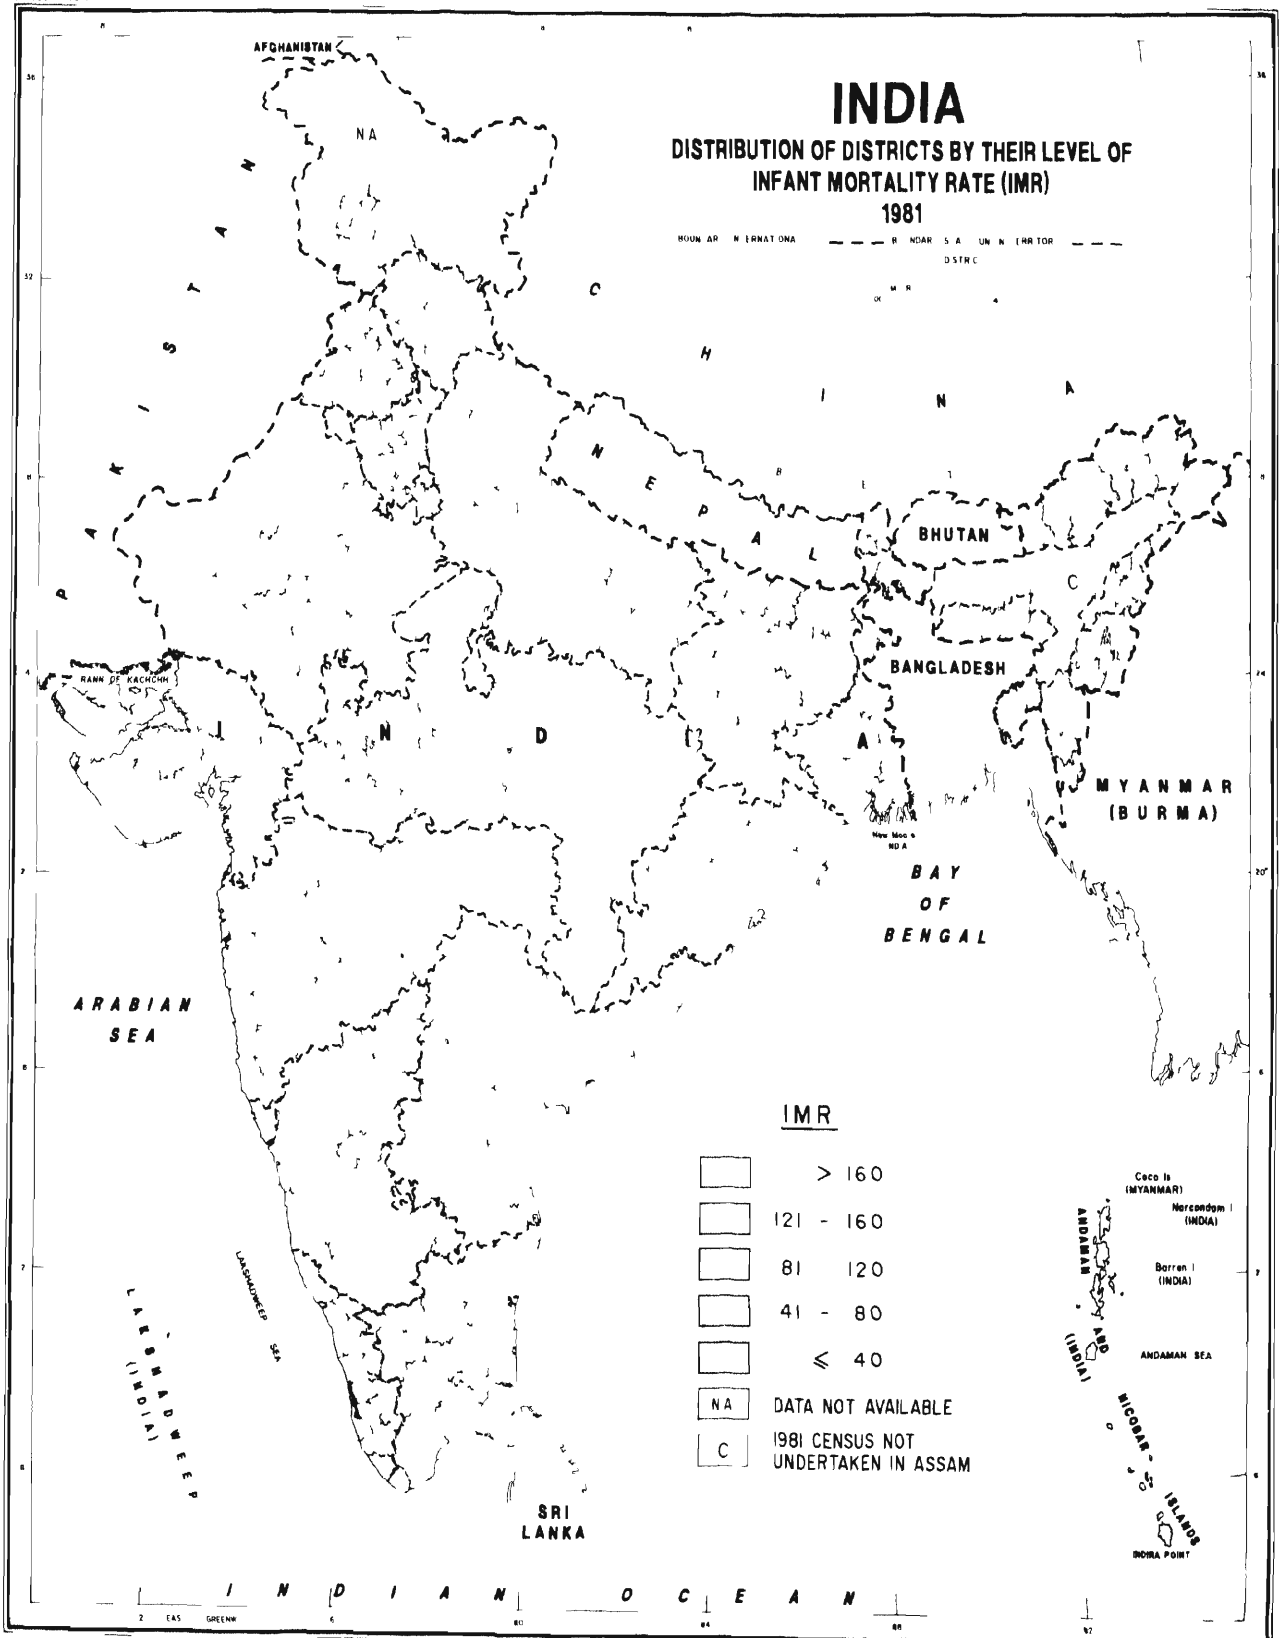

The districts with IMRs over 120 are mostly located in Uttar Pradesh, Madhya Pradesh, Bihar, and Orissa (see Map 2). Surprisingly, there are also many districts in Gujarat with high IMRs. Perhaps equally surprising is that relatively few districts in Rajasthan have IMRs over 120. All of the districts with IMRs greater than 160 are found in Uttar Pradesh and Madhya Pradesh except for East Kameng and Upper Subansiri districts in Arunachal Pradesh.

Kerala has the lowest levels of infant mortality in the country. Western Maharashtra, Karnataka, Nagaland, Manipur, Mizoram also have relatively low infant mortality, as do many districts in Jammu and Kashmir, Himachal Pradesh, Punjab, Rajasthan, Arunachal Pradesh, and Western Bengal.

**Table 12. Intra-state Variability in the Infant Mortality Rate
Major States of India, 1981**

| State | Infant Mortality Rate | | | | |
|------------------|-----------------------|-------|-------|------|------|
| | TFR | Min. | Max. | S.D. | C.V. |
| Andhra Pradesh | 86.0 | 29.7 | 123.5 | 18.2 | 21.1 |
| Bihar | 118.0 | 67.9 | 150.7 | 16.2 | 13.8 |
| Gujarat | 116.0 | 88.8 | 145.3 | 18.3 | 15.8 |
| Haryana | 101.0 | 80.2 | 122.0 | 12.0 | 11.9 |
| Himachal Pradesh | 71.0 | 51.4 | 105.4 | 16.0 | 22.5 |
| Jammu & Kashmir | 72.0 | 43.7 | 141.9 | 21.9 | 30.5 |
| Karnataka | 69.0 | 40.2 | 86.9 | 9.9 | 14.4 |
| Kerala | 37.0 | 25.6 | 57.4 | 9.7 | 26.2 |
| Madhya Pradesh | 142.0 | 80.3 | 181.6 | 21.9 | 15.4 |
| Maharashtra | 79.0 | 48.8 | 115.5 | 18.5 | 23.5 |
| Orissa | 135.0 | 104.2 | 156.9 | 17.7 | 13.1 |
| Punjab | 81.0 | 70.0 | 91.8 | 6.0 | 7.4 |
| Rajasthan | 108.0 | 57.4 | 142.5 | 21.4 | 19.8 |
| Tamil Nadu | 91.0 | 53.9 | 110.7 | 15.5 | 17.0 |
| Uttar Pradesh | 150.0 | 85.0 | 212.5 | 25.8 | 17.2 |
| West Bengal | 91.0 | 45.7 | 127.2 | 23.0 | 25.2 |

Note: Coefficient of Variation (C.V.) is calculated with respect to our state level IMR estimates rather than the mean of IMRs for districts in each state.

Based upon Survey of India map with the permission of the Surveyor General of India

The territorial waters of India extend to the sea to a distance of twelve nautical miles measured from the appropriate baseline

For the country as a whole, the infant mortality rate ranged from a low of 26 for Kottayam district in Kerala to a high of 212 for Hardoi district in Uttar Pradesh. The few districts with IMRs less than 40 are Hyderabad district in Andhra Pradesh; Cannanore, **Kozhikod**, Trichur, Ernakulam, Kottayam, Alleppey, Quilon, and Trivendrum districts in Kerala; Manipur South and Manipur Central districts in Manipur; and Wokha district in Nagaland. At the other extreme, the districts with an IMR over 200 were Badaun and Hardoi districts in Uttar Pradesh, and East Kameng in Arunachal Pradesh.

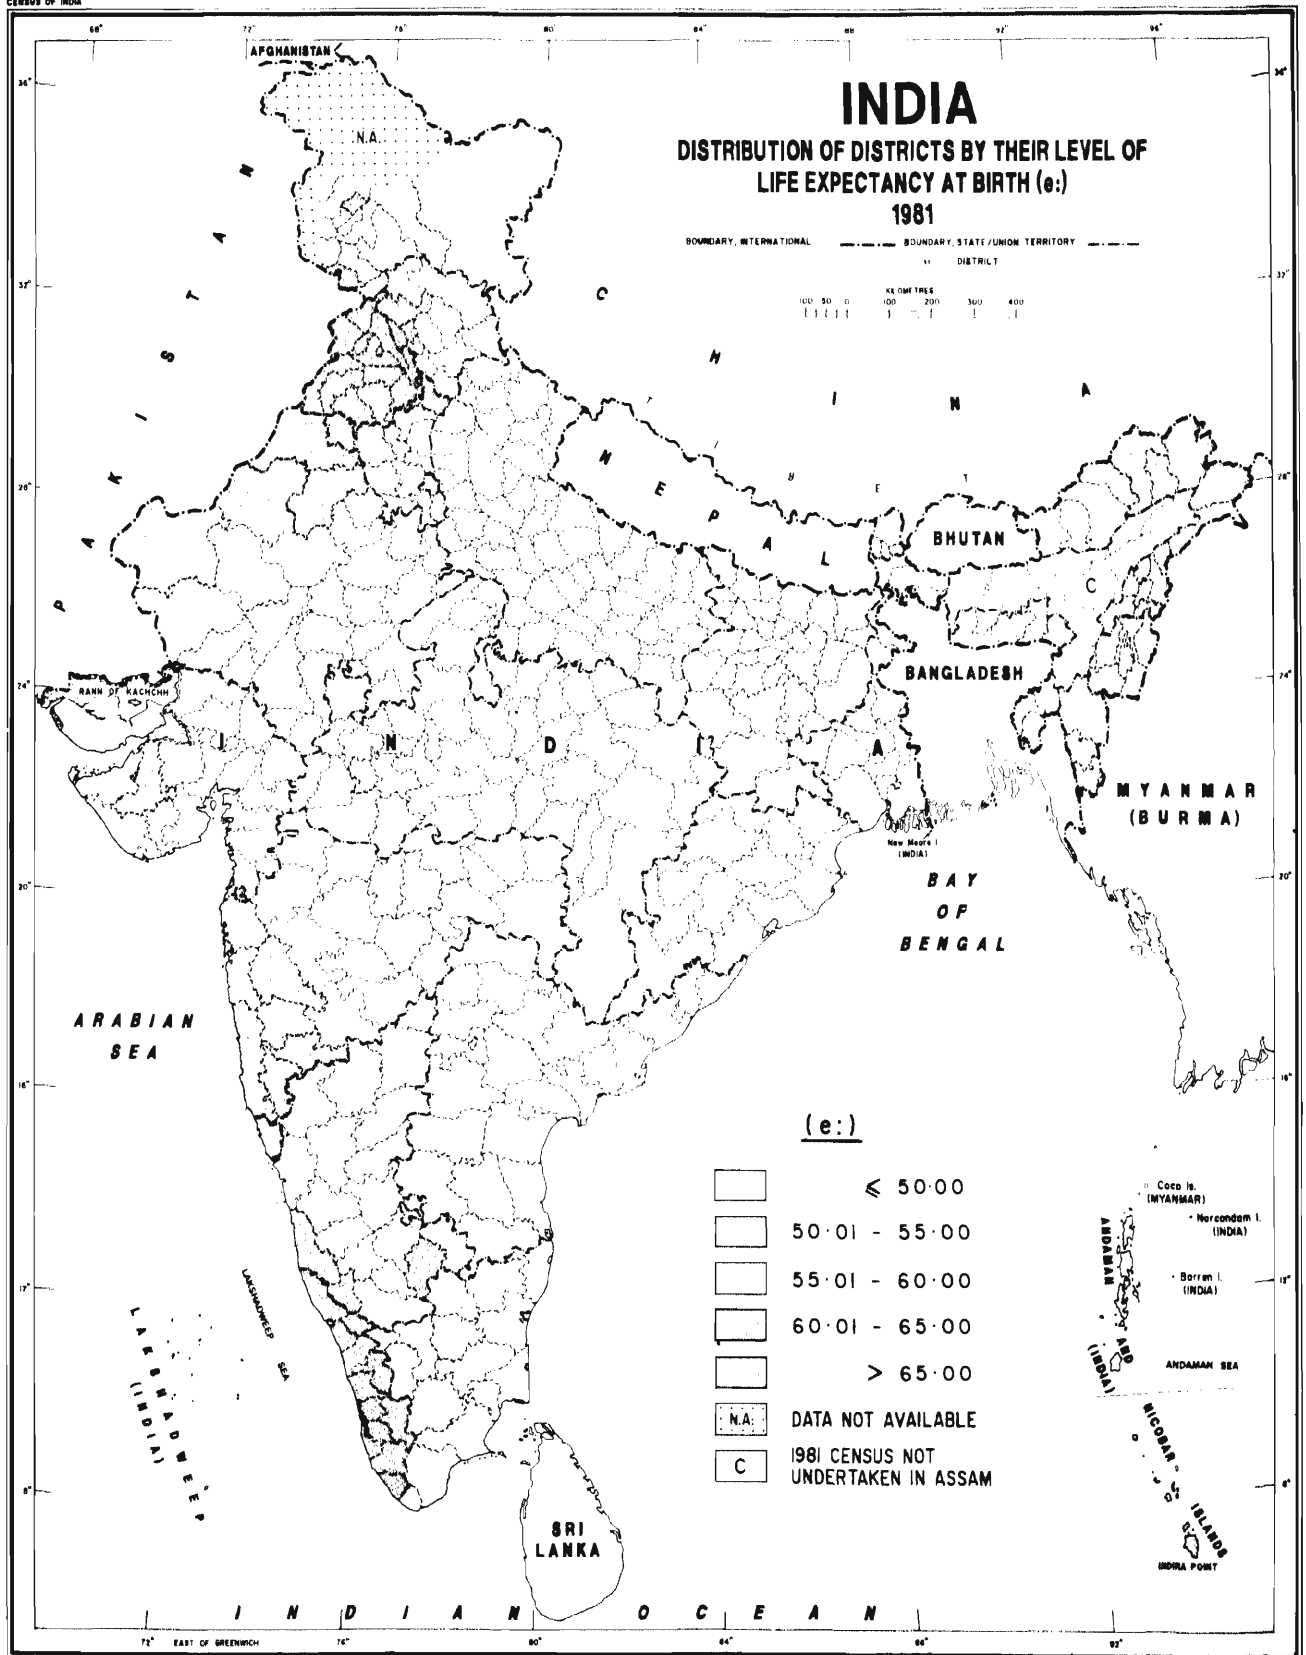

Turning now to our other mortality estimate, the life expectancy at birth, we found that about one third of all the districts in India in 1981 had a life expectancy at birth less than 50 years and only eleven districts had an e_0 greater than 70 years (Table 13). Roughly half of the districts had an e_0 between 50 and 60 years. For the country as a whole, the 1981 district-level life expectancy at birth ranged from 38.2 years for Hardoi district in Uttar Pradesh to 75.0 years for Manipur Central district in Manipur.

The districts with expectations of life less than 50 years are mostly in Uttar Pradesh, Madhya Pradesh, Bihar, and Orissa (see Map 3). The areas with relatively high life expectancy are the entire states of Kerala, Punjab, Nagaland, Manipur, and Mizoram, and the districts in western Rajasthan and western Maharashtra. From both the map and Table 14, one can see wide variability in the e_0 values.

Table 13. Distribution of Districts by the Level of Expectation of Life at Birth, India, 1981

| Expectation of Life at Birth (e_0) | Number of Districts | Percentage |
|--|----------------------------|-------------------|
| 40 and under | 4 | 1.0 |
| 40 - 45 | 21 | 5.2 |
| 45 - 50 | 97 | 24.1 |
| 50 - 55 | 88 | 21.9 |
| 55 - 60 | 103 | 25.6 |
| 60 - 65 | 56 | 13.9 |
| 65 - 70 | 22 | 5.5 |
| 70 - 75 | 10 | 2.5 |
| 75 and above | 1 | 0.2 |
| Total | 402 | 100.0 |

The districts with higher mortality rates (lower e_0 values) are generally found in Bihar, Madhya Pradesh, Orissa, Uttar Pradesh, West Bengal, Rajasthan, and Tamil Nadu. Districts in Bihar, Orissa, and Uttar Pradesh have the lowest e_0 values. To give an example from just one of these states: twenty-nine of the thirty-one districts in Bihar had 1981 life expectancies less than 50. At the other extreme, all of the districts in Kerala and Punjab have life expectancies over 60 (Table 14).

Based upon Survey of India map with the permission of the Surveyor General of India.

The territorial waters of India extend into the sea to a distance of twelve nautical miles measured from the appropriate base line.

Table 14. Distribution of Districts by Their Level of Expectation of Life at Birth for Major States of India, 1981

| State | Number of Districts with e_0 | | | | |
|------------------|--------------------------------|---------|---------|---------|--------|
| | ≤ 50 | 50 - 55 | 55 - 60 | 60 - 65 | > 65 |
| Andhra Pradesh | 3 | 5 | 14 | 0 | 1 |
| Bihar | 29 | 2 | 0 | 0 | 0 |
| Gujarat | 0 | 1 | 17 | 1 | 0 |
| Haryana | 0 | 2 | 9 | 1 | 0 |
| Himachal Pradesh | 1 | 3 | 4 | 4 | 0 |
| Jammu & Kashmir | 1 | 1 | 10 | 2 | 0 |
| Karnataka | 0 | 1 | 15 | 2 | 1 |
| Kerala | 0 | 0 | 0 | 3 | 9 |
| Madhya Pradesh | 25 | 17 | 2 | 1 | 0 |
| Maharashtra | 3 | 6 | 10 | 6 | 1 |
| Orissa | 8 | 2 | 3 | 0 | 0 |
| Punjab | 0 | 0 | 0 | 12 | 0 |
| Rajasthan | 6 | 11 | 5 | 3 | 1 |
| Tamil Nadu | 0 | 11 | 4 | 1 | 0 |
| Uttar Pradesh | 41 | 13 | 2 | 0 | 0 |
| West Bengal | 2 | 10 | 3 | 1 | 0 |

The intra-state variability in the district e_0 levels is highest in Rajasthan, where the district-level life expectancies at birth range from 45.4 years for Tonk district to 65.1 years for

Bikaner district (Table 15). Relatively high within state variability is also found in Uttar Pradesh, Himachal Pradesh, Jammu and Kashmir, Maharashtra, and Madhya Pradesh.

| Table 15. Intra-State Variability in Life Expectancy at Birth, Major States of India, 1981 | | | | | |
|---|---|-------------|-------------|-------------|-------------|
| State | Life Expectancy at Birth (e₀) | | | | |
| | e₀ | Min. | Max. | S.D. | C.V. |
| Andhra Pradesh | 55.0 | 47.7 | 67.8 | 3.7 | 6.6 |
| Bihar | 46.5 | 42.2 | 53.6 | 1.8 | 3.9 |
| Gujarat | 56.1 | 51.8 | 60.2 | 2.0 | 3.7 |
| Haryana | 55.8 | 51.5 | 60.2 | 2.7 | 4.8 |
| Himachal Pradesh | 56.7 | 46.8 | 62.7 | 4.8 | 8.5 |
| Jammu & Kashmir | 57.7 | 42.8 | 64.6 | 4.7 | 8.2 |
| Karnataka | 57.7 | 53.2 | 65.6 | 2.4 | 4.1 |
| Kerala | 67.3 | 61.2 | 71.2 | 3.1 | 4.6 |
| Madhya Pradesh | 49.7 | 42.9 | 61.3 | 4.0 | 8.1 |
| Maharashtra | 57.8 | 48.9 | 65.8 | 4.7 | 8.2 |
| Orissa | 49.8 | 46.2 | 56.1 | 3.6 | 7.1 |
| Punjab | 61.7 | 60.4 | 64.2 | 1.0 | 1.7 |
| Rajasthan | 53.0 | 45.4 | 65.1 | 5.2 | 9.9 |
| Tamil Nadu | 53.6 | 53.0 | 60.8 | 2.2 | 4.0 |
| Uttar Pradesh | 47.0 | 38.2 | 57.1 | 4.3 | 9.2 |
| West Bengal | 51.7 | 45.6 | 60.3 | 3.7 | 7.1 |

Note: Coefficient of Variation (C.V.) is calculated with respect to our state level e₀ estimates rather than the mean of e₀ values for districts in each state.

The lowest intra-state variability is observed in Punjab where all of the districts have life expectancies between 60 and 65 years.

Discussion and Conclusions

The main result from this work is the series of new fertility and mortality estimates for each district, presented in Appendices I and II. While useful in their own right, these numbers will become even more useful after a similar study is completed when the appropriate 1991 Census data become available.

The new district-level estimates presented in this report are almost certainly more valid than the Brass method estimates published earlier for the reasons enumerated earlier in this report. Nevertheless, these new estimates should also be interpreted and used with some caution. They are, after all, *estimates* rather than actual fertility and mortality rates resulting from the combination of complete and reliable vital registration of births and deaths and good census data.

The district-level fertility estimates should be viewed with particular caution under the following four conditions:

if migration into or out of the district was particularly heavy in the five to ten years before the 1981 Census (because heavy migration affects the age and sex distribution of the district's population);

- if the age and sex distribution data for the district is especially inaccurate because of under-enumeration of particular age groups or females or males, age mis-statement, or other reasons;
- if the district has cultural norms that make it uncommonly likely to under-report children ages 0-4; and
- if the mortality estimates for the district are inaccurate, since all three regression methods use a mortality indicator as an input variable;

The district-level mortality estimates are, of course, most likely to be wrong if there were reporting errors in the 1981 Census on the special questions on children ever born and children surviving.

Acknowledgements

This paper resulted from cooperative research between the Office of the Registrar General, India, and the Program on Population, East-West Center, Honolulu, Hawaii, U.S.A., partially funded by the United States Agency for International Development. The authors are thankful to A. R. Nanda, Registrar General and Census Commissioner, India, and Andrew Mason, Director, Program on Population, East-West Center, for their support and encouragement. The authors also acknowledge helpful discussions and comments from Robert Retherford, V. S. Swamy, and A. K. Saxena. Jean Zhou provided excellent clerical assistance.

The views expressed in this report are those of the authors alone and do not necessarily represent those of the organizations in which they work.

IMR and e_0 estimates for major states are same as SRS estimates because for major states estimates derived from the South Asian Model Life Tables have been adjusted for SRS levels. For smaller states and union territories the IMR and e_0 estimates could not be adjusted to SRS levels due to the non-availability of corresponding SRS estimates.
